M.R. Alderson, Inst. of Cancer Research, Division of Epidemiology, *Clifton Ave., Sutton SM2 5PX, England, United Kingdom* (D-IARC-79-691)

This study will examine the relative risk of lung cancer in process workers in the bichromate industry, taking account of factory of employment, calendar period, and duration of employment. A group of workers initially studied in the 1950's will be followed, together with those workers who have since entered three factories in the United Kingdom. All workers leaving this industry will be traced to provide 30 yeer follow-up for some workers. Limited data will be available on the specific tasks carried out by individual workers.

FILTER TIP CIGARETTE SMOKING

M.R. Alderson, Inst. of Cancer Research, Division of Epidemiology, *Clifton Ave., Sutton SM2 5PX, England, United Kingdom* (D-IARC-79-690)

This study will examine the influence of filter tip cigarette smoking in comparison with plain cigarettes upon the relative risk of lung cancer, chronic bronchitis, ischemic heart disease, and cerebrovascular disease. Two hundred patients of each sex in the age groups 35-, 45-, 55-, and 65-74 for the four diseases are being studied and equal numbers of controls will be interviewed at ten major centers treating these conditions throughout England. The data collected by trained interviewers will include information on long-term smoking patterns, place of

residence, occupation, and other confounding factors.

2.1487,
COLLATION OF ROUTINE STATISTICS
M.R. Alderson, Inst. of Cancer Research, Division of Epidemiology, *Clifton Ave., Sutton SM2 5PX, England, United Kingdom* (D-IARC-79-693)
This project will collate, analyse, present and interpret routine mortality and morbidity statistics for England and Wales and selected other countries to provide (1) specific statistics required for particular studies carried out by the divisions of epidemiology, and (2) a background to consideration of the epidemiology and health care problems of cancer. Use will be made of national mortality (annual statistics, and decennial supplements on occupational and area mortality); incidence data (including unpublished analyses of occupation); hospital treatment data (from the hospital inpatient inquiry); workload and facilities (from health and personal social service statistics). Equivalent material from other national offices of vital statistics, WHO and IARC will be examined for selected countries. Many of the issues being considered require data from a non-malignant disease (e.g., time trends in stomach cancer in relation to large bowel cancer, peptic ulcer and other alimentary disease); statistics for about 30 non-malignant diseases will therefore be included in the project.

2.1488,
AETIOLOGICAL FACTORS IN BREAST CANCER
M.R. Alderson, Inst. of Cancer Research, Division of Epidemiology, *Clifton Ave., Sutton SM2 5PX, England, United Kingdom* (D-IARC-79-694)
This project will explore the relationship between history of psychiatric illness, social and emotional adjustment, and exposure and reaction to defined 'life crises' and the relative risk of breast cancer. Women attending an early diagnosis unit will be interviewed and, thus, data will be available on those subsequently found to have breast cancer compared with those with benign and no overt breast lesions. Additional data will be collected from other control patients attending the hospital.
SUPPORTED BY (No Supporting Organization Reported) funds n.a.

2.1489,
MORTALITY OF MILLERS AND BAKERS
M.R. Alderson, Inst. of Cancer Research, Division of Epidemiology, *Clifton Ave., Sutton SM2 5PX, England, United Kingdom* (D-IARC-79-687)
This study will examine the mortality of a group of grain millers followed from 1961-1976 and compare their causes of death with those of bakers and the general population over this period. The 1961 census will be used to identify all individuals in the general category of food processors and the specific category of bakers and pastry cooks. These records will be examined by Office of Population Census and Survey staff to identify those who recorded their occupation as grain miller at the time of the census, together with the records for male bakers and pastry cooks. These individuals will be traced through the National Health Service Central Register to identify those who have died and obtain the cause of death.
SUPPORTED BY (No Supporting Organization Reported) funds n.a.

2.1490,
MORTALITY OF HAIR DYERS AND TINTERS
M.R. Alderson, Inst. of Cancer Research, Division of Epidemiology, *Clifton Ave., Sutton SM2 5PX, England, United Kingdom* (D-IARC-79-689)
This study will examine the mortality of a group of hair dyers and tinters followed from 1961 to 1976 and compare their causes of death. Census data will be used to identify a sample of all hairdressers throughout England and Wales; the staff from the Office of Population Census and Survey will identify individuals specifically describing themselves as hair dyers and tinters at the time of the census. These individuals will be traced through the National Health Service Central Register and for those that have died the cause of death will be released. The all-cause mortality, mortality from malignant disease and from other diseases will be examined.
SUPPORTED BY (No Supporting Organization Reported) funds n.a.

2.1491,
FOLLOW-UP OF PATIENTS TREATED FOR MALIGNANT DISEASE
M.R. Alderson, Inst. of Cancer Research, Division of Epidemiology, *Clifton Ave., Sutton SM2 5PX, England, United Kingdom* (D-IARC-79-688)
This study will follow large groups of patients treated by radiation to identify those dying from a second malignancy and also follow adolescents and young adults treated with increasingly powerful schedules to quantify the mortality from second malignancies and to check whether there is any evidence of a carcinogenic or teratogenic effect following conception. For both these groups of patients the original medical records will be abstracted; this will include detailed data on initial and subsequent treatment. Where patients have been followed until death, the cause of death will be obtained, whilst those known to be alive will be included, particular effort being made to trace patients presently lost to follow-up. Survivors from adolescence will be interviewed when they have reached child-bearing age, and a marital history will be obtained including data on any conception that occurs. Information about miscarriage, stillbirth, or children born with congenital abnormalities will be sought; live-born children will be followed to identify the incidence of malignancy.

2.1492,
INFLAMMATORY BOWEL DISEASES AND CANCER
R.N. Allan, General Hospital of Birmingham, *Steelhouse Ln., Birmingham B4 6NH, England, United Kingdom* (D-IARC-79-568)
A survey is in progress to monitor the appearance of cancer in a hospital-based series of patients with chronic inflammatory bowel diseases (Crohn's Disease, coeliac disease and ulcerative colitis). The patients have been under continuous surveillance for periods of up to 30 years and the development of subsequent cancers has been recorded. The number of tumors which might be expected to occur in the series is computed from person-years of observation together with cancer incidence rates based on data from the Birmingham Regional Cancer Registry.

INFECTION WITH HEPATITIS B VIRUS IN RELATION TO HEPATOCELLULAR CARCINOMA
A.C. Bayley, University of Zambia, School of Medicine, Dept. of Surgery, *P.O. Box 2379, Lusaka, Zambia* (D-IARC-79-1092)
Hepatocellular carcinoma is the most common tumour of Zambian men. A recent study of 19 patients treated in Lusaka and of 40 control villagers living in the Eastern Province showed that all patients and 63% of controls showed serological evidence of past infection with hepatitis B virus (HBV), usually antibody to surface antigen. The objectives of this study are: (1) To record the prevalence of HB surface antigen (HBsAG) antibody to this antigen, and antibody to core antigen in the serum of selected Zambians of all age groups; (2) to investigate serial blood samples from apparently healthy individuals with serological evidence of past or present infection with HBV; (3) to examine cord blood at birth for evidence of exposure to HBV and to follow up the babies of HBsAG-positive mothers to determine if and when serological evidence of infection develops; (4) to investigate the pattern of antibody production to surface and core antigens following exposure to infection at work (surgeons) and by transfusion (children); (5) to compare the prevalence of HBsAG and antibody to core and surface antigens in persons in villages where hepatoma has and has not been observed in the last five years; (6) to identify men with a high risk of developing hepatocellular carcinoma for regular screening. Control villages and 'hepatoma' villages have been selected close to a well established mission hospital. It is planned to attempt to obtain three serum samples from each of 500 individuals over the age of three years during a period of two consecutive years.

PREVALENCE OF ASBESTOSIS, PLEURAL CHANGES AND MALIGNANT NEOPLASMS IN BLACK EX-MINERS AND FEMALE COBBERS
W.O. Harrison, South African Medical Research Council, National Research Inst. for Occupational Diseases, Dept. of Occupational Medicine, *Joubert St. Ext., Johannesburg 2001, Transvaal, South Africa* (D-IARC-79-485)
In 1973 the National Research Institution for Occupational Diseases was approached to determine the state of health of ex-employees of the asbestos mining industries, especially those using Cape crocidolite. Based at the St. Michael's Hospital at Bathlaros, near Kuruman, in the North West Cape Province, a small clinic was established, staffed by a doctor, nurse and a driver who knew the country and were well known in it. With the assistance of the Bureau of Census and Statistics mining company records were investigated. By August 1977 some 1500 ex-employees had been traced. At present attention is concentrated on investigating a cohort of ex- and current employees exposed during 1957-1962.

A STUDY OF THE RELATIONSHIP OF MALIGNANT DISEASE IN CHILDHOOD TO OTHER DISORDERS AND CHARACTERISTICS

I. Leck, Christie Hospital & Holt Radium Inst., Regional Cancer Epidem Unit, *Wilmslow Rd., Withington, Manchester M20 9BX, England, United Kingdom* (D-IARC-78-595)

The study is based on the records of the University of Manchester Children's Tumor Registry which include: (1) extensive clinical, pathological, familial and demographic data on cases of neoplasms that have been presented since 1954 in a population of approximately one million children under 15 years of age in northwest England, and (2) some comparable data for matched controls. This material is being analyzed with reference to: (1) incidence of childhood neoplasms by histological type, site, age at onset and sex; (2) distribution of cases in space and time; (3) possible variations in incidence with personal and family circumstances including incidents during the relevant pregnancy; (4) associated pathology in the children and their relatives; (5) health of long-term survivors and their progeny.

DEMOGRAPHIC CANCER STUDIES IN NORTHERN SWEDEN

L.G. Larsson, Regionsjukhuset, Dept. of Oncology, *58185 Linkoping, Sweden* (D-IARC-79-525)

Northern Sweden exhibits some interesting features for geographical and epidemiological cancer studies as it contains several well separated and, from the socioeconomic and industrial point of view, different regions. There exist towns with a very low degree of industrialization, others being heavily industrialized, large rural areas and some rather specific industrial sites such as the mining districts in Norrbotten and Vaesterbotten. The study is based on morbidity and mortality data from the Swedish Cancer Registry and the Swedish Death Registry and will cover the years 1959-1971. The first part of the project involves calculation of age-adjusted incidences for different cancer sites for comparison by small geographic regions (towns, communes, parishes) in the three most northern counties (Vaesternorrland, Vaesterbotten and Norrbotten). Commune-based age-adjusted incidence rates have so far been calculated for lung cancer and female breast cancer. In both cases significant differences between communes were found which now are the subject of further studies. Incidence data for other cancers will also be produced. The findings concerning female breast cancer have been published in Swedish (Swedish Society of Medical Radiology. Proc. no.8, 1977) and will soon appear in more detailed form in English (Acta Radiol. Ther.). The findings concerning male lung cancer and female breast cancer will soon be published in Nordic Council for Artic Medical Research, report 21. An atlas containing data for all more frequent cancer types will probably be published during 1979. Work continues.

FREQUENCY OF SELECTED CANCERS - USE OF A COMPUTERIZED RETRIEVAL SYSTEM

W. Isarangkul Na Ayuthya, Mahidol University, School of Medicine, Dept. of Pathology, *Bangkok, Thailand* 7 (D-IARC-79-544)

The frequency and age distribution of the female reproductive tract cancers are being studied as part of the utilization of a computerized tumor data base designed to permit instant retrieval of selected diagnoses. This project, in the past, handled only material from Ramathibodi Hospital, but has now been extended to cover material submitted from elsewhere in Thailand. So far all the tumor data from 1974 to 1977 have been processed. After the processing of the 1978 data is completed the annual frequency and age distribution of cancers of all sites from 1974 to 1978 will be studied with an emphasis on the female genital tract cancers. With use of the SNOP coding system the frequencies of specific types of cancers can be studied in addition to the overall frequency of all cancers of a particular site. The distribution of both age and frequency will be obtained automatically.

RELATIONSHIP BETWEEN CUMULATIVE DUST EXPOSURE AND DEVELOPMENT OF ASBESTOSIS AND PLEURAL CHANGES IN ASBESTOS MINERS

L.M. Irwig, South African Medical Research Council, National Research Inst. for Occupational Diseases, Dept. of Epidemiology, *Joubert St. Ext., Johannesburg 2001, Transvaal, South Africa* (D-IARC-79-486)

This survey, one of the projects dealing with exposure to asbestos dust, currently consists of the retrospective and prospective recording of the dust exposure of 2,000 white asbestos miners. Records are updated at intervals by the particular inspector of mines of the area. The cumulative dust exposure records are correlated with X-ray changes or, if death occurs, with the findings at autopsy. The radiological appearances are read by three readers, but checks for inter-observer error are made. Correlation of the pathological changes will start during this year and, where possible, dust will be extracted from the lungs for comparison with the dust exposure records. It has not yet been possible to include black mine workers in the survey although the conversion factors to convert the mine mean into an occupational exposure have been assessed. The employment of migrant labour makes the follow-up of the black worker difficult, but more active steps must be taken to find some way of adding this large group to the survey.

TUMORS IN CHILDREN - SEX- AND AGE-SPECIFIC INCIDENCE RATES IN RELATION TO HISTOGENESIS

J. Powell, Regional Cancer Registry, *c/o Queen Elizabeth Med. Ctr., Birminghan B15 2TH, England, United Kingdom* (D-IARC-79-572)

Tumors in children differ sharply from those of the adult, particularly in the systems of the body in which they most commonly occur. Examination of sex- and age-specific incidence rates (for single years from birth) indicate the well-known marked variations during the first decade of life, although from age ten onwards the difference between childhood and adult cancer becomes one of quantity rather than quality. A method of classification according to histogenesis has been developed and, since the data are from a population-based registry, variation in the age at onset appears to provide a useful model for studying the relationship between the different types of malignancy and possible aetiological factors, the organs affected depending in some types on the gestational age of exposure.

EPIDEMIOLOGICAL ANALYSIS OF LARGE BOWEL CANCERS BY SUBSITE DISTRIBUTION - - AGE AND SEX PARAMETERS OF DIAGNOSIS AND SURVIVAL

J. Powell, Regional Cancer Registry, *c/o Queen Elizabeth Med. Ctr., Birminghan B15 2TH, England, United Kingdom* (D-IARC-79-573)

Variations in morbidity between the sexes and at different ages could indicate possible aetiological factors, provided there is no bias due to incomplete registration or inaccurate diagnosis. Registration in the West Midlands has been virtually complete for over fifteen years and the region has a high standard of medical care so that even in patients too advanced for treatment there are facilities for an accurate assessment of the primary site. Moreover, in a population of 5.2 million, over 2,000 cases of large bowel carcinoma are registered each year. Hence, chance variations due to small numbers are minimised. Fortunately a single anatomical site code has been in use for the whole period and the subdivisions are sufficiently fine to permit examination of incidence rates by finer divisions of the colon than is possible with the present ICD code. Preliminary examination of incidence rates by age, sex and site of primary indicates in some cases marked similarities and in others marked differences between different segments of both the colon and rectum.

2.1507,

MULTIPLE PRIMARY MALIGNANT TUMOR SURVEY

M.P. Prior, Regional Cancer Registry, *c/o Queen Elizabeth Med. Ctr., Birminghan B15 2TH, England, United Kingdom* (D-IARC-79-574)

An analysis of population-based data, collected at the Birmingham Regional Cancer Registry, is being carried out to determine whether there is any evidence of an increased risk of a second primary over that of a first, in terms of either site-specific associations or high-risk groups. The results may help to define aetiological factors in tumour development and to identify individuals 'at risk' who will benefit from increased surveillance. The method of analysis is similar to previous surveys in that an index site is selected, and observed numbers of second primary tumours are compared with expected numbers computed from incidence rates for the regional population. Special consideration has been given to fundamental methodology related to coincidental diagnoses and to the sequence of tumours. The emphasis has been, therefore, on 'site-pair' analysis, that is on investigating each sequence for a pair of sites, in contrast to the conventional approach which considers one index site in relation to all second primary sites. A major survey of bilateral breast cancer over a period of nearly 30 years has been undertaken and the interrelationships between breast and female reproductive sites have been investigated. Current work includes analyses for lung in association with male reproductive sites, and also with bladder. Future projects will include the addition of large bowel tumours to the spectrum of paired analyses.

CAUSES OF MORTALITY AND DISABILITY IN FERRO-ALLOY WORKERS

L.V. Pokrovskaya, Sverdlovsk Research Inst. of Hygiene of Labor & Occup. Dis., Dept. of Industrial Hygiene, *Repin 2, Sverdlovsk 620014, Russian, Union of Soviet Soc. Republics* (D-IARC-79-1083)

Previous work has shown that the mortality from cancer in workers handling chrome-containing ferro-

alloys is significantly higher than in the general population. These workers had a heavy exposure not only to chrome compounds but also to polycyclic aromatic hydrocarbons (PAH), especially benz(a)pyrene. The present study aims to explore the causes of death and disability among smelters of various ferro-alloys (exposed not to chrome but to PAH), particularly from malignant lymphoma and leukaemia. The follow-up of the cohort began in 1955 and continued until 1974.

MORTALITY AND CANCER MORBIDITY IN AN AREA SURROUNDING AN ARSENIC EMITTING SMELTERY

B.G. Pershagen, Karolinska Institutet, Dept. of Environmental Hygiene, *Solnavagen 1, S10401 Stockholm 60, Sweden* (D-IARC-79-520)

The purpose of the investigation is to determine whether an increased mortality and/or cancer morbidity exists in an area around the Roennskaersverken smelter works in northern Sweden. Founded in 1929, this metallurgical plant, processing mainly non-ferrous metals, has, since the start of operations, used ore with a high arsenic content. This has resulted in pollution of air and water by arsenic as well as by other metals and sulphur dioxide. The investigation is in the form of cohort study. The exposed comprise the population of two parishes in the vicinity of the plant, defined from the National Census in 1960. reference population in the same part of Sweden with a similar degree of urbanization, occupational profile and age distribution was chosen. The causes of death and cancer morbidity for the two populations are to be followed up over a period of 14 years. Results from a pilot study have shown a significantly higher mortality rate for lung cancer in men in the exposed area. However, this increase was no longer significant when the occupationally exposed at Roennskaersverken were excluded. The latter showed a highly significant excess mortality from primary respiratory cancer. The smoking habits in the two populations will be studied using a case-control method.

PROSPECTIVE AND RETROSPECTIVE COHORT STUDIES OF MORTALITY AND MORBIDITY AMONG SWEDISH CHEMISTRY GRADUATES

R.G. Olin, Kungliga Tekniske Hogskolan, Dept. of Safety & Health, *S10044 Stockholm 70, Sweden* (D-IARC-79-519)

The causes of death among chemists who belonged to a cohort of men who graduated from the School of Chemical Engineering at the Royal Institute of Technology in Stockholm during the years 1930-1960 were studied. The group was followed until the end of 1977. Results to date show a significant increase in cancers, particularly malignant lymphomas and brain and prostate neoplasms in comparison with the causes of death in the general population, as well as in a similar cohort of architects educated at the same school during the same period of time. The study is at present being continued prospectively. The surviving male chemists have been sent a questionnaire concerning exposures and health effects; the participation rate is about 85%.

THE FREQUENCY OF SKIN CARCINOMA IN THE REGION OF RIJEKA (YUGOSLAVIA)

N. Mohar, Clinic of Dermatovenerology, *D. Tucovica 15, c/o Clin. Hos. Braca Dr. Sobol, 51000 Rijeka, Yugoslavia* (D-IARC-79-1091)

The characteristics of 1,016 persons with cancer of the skin treated at Rijeka, Yugoslavia, in 1965-1974 have been analyzed. Representing 18% of all forms of cancer, 953 patients had solitary and 63 multiple lesions. Basal cell carcinoma was diagnosed histologically in 748 instances (67.6%), squamous cell carcinoma in 296 (26.7%) and mixed forms in 62 (5.6%). Basal cell carcinoma was more frequent in women (409), squamous cell carcinoma in men (181) due to a greater frequency of lip neoplasms (80). In 89.9% carcinomas were located on exposed parts of the body and only in 18% on covered parts. The frequency of the disease was highest among housewives (360 or 35.4%) who, in many instances, had migrated to the city from villages. There were a large number of seamen, fishermen (288 or 28.3%), laborers, longshoremen and masons. Farmers repesented only 10.2% or 104 cases. Previous trauma was noted in 314 cases (30.9%). The study continues.

2.1512,

ECOLOGICAL AND PATHOPHYSIOLOGICAL STUDIES OF PRIMARY LIVER CELL CARCINOMA IN RELATION TO LOCAL THAI FOOD PRODUCTS

P. Migasena, Mahidol University, School of Tropical Medicine, Dept. of Tropical Nutrition & Food Science, *420/6 Rajavithi Rd., Bangkok 4,, Thailand* (D-IARC-79-545)

Primary liver cell carcinoma is one of the most common causes of mortality in Thailand especially in the northeast region. The incidence rate is five times that of western countries. The age at diagnosis is generally younger than 40 and the youngest reported case was 11 years old. It is suggested that the cause may be associated with food. Plara is a fermented fish product which is prepared locally and consumed by Thai people throughout Thailand, particularly in the North and Northeast. During the preparation of plara, which is sometimes stored for a period of years, secondary and tertiary amines are probably formed and these amines may react with nitrates or nitrites which are present as contaminants in salt or water to form nitrosamines which are known carcinogens. The main objectives of the present studies are to (1) bioassay by feeding the local food product to animals to observe the toxic effects; (2) investigate, both quantitatively and qualitatively, nitrosamines, nitrates and nitrites in Thai food products and (3) study serum protein patterns and some single protein fractions such as proteinase inhibitor by polyscrylamide gel electrophoresis and immunoelectrophoresis from clinically diagnosed primary liver cell carcinoma cases compared to other hepatic diseases, such as liver cirrhosis, hepatitis and opisthorchiasis in order to better understand the pathophysiology of the disease. At the same time, the studies are designed to determine the geographic, cultural and social relationship of this cancer with the food consumption patterns of the population.

FIBRE EXPOSURE, MORTALITY AND RADIOGRAPHIC CHANGES IN QUEBEC CHRYSOTILE PRODUCTION INDUSTRY

J.C. McDonald, University of London, London School of Hygiene & Tropical Medicine, T.U.C. Centenary Inst. of Occupational Health, *Keppel St., London WC1E 7HT, England, United Kingdom* (D-IARC-79-634)

OBJECTIVES: (1) With exposure expressed in terms of fibres per ml, averaged over time, and account taken of date of birth, age first employed, duration of employment and smoking habits to determine whether exposure discriminates between (a) men who died from selected causes and others who survived to the same ages; (b) various types of radiological outcome in men aged 45-64, employed 30 years or more. If either is so, the relative risks associated with increasing average fibre concentrations will be eliminated. (2) To determine whether and in what way the subsequent experience of chrysotile asbestos workers is related to the presence or absence in past records of (a) changes observed in routine chest x-rays taken at work, (b) impaired pulmonary function and (c) respiratory symptoms. (3) (a) To determine whether there is any important difference in the chest x-ray appearances by rate and type of change between men without other occupational dust exposure who were employed at least 10 years wholly in companies mining slip fibre or in companies mining cross fibre; (b) to describe quantitatively and qualitatively the dust and fibre exposure experienced by both groups of men.

STUDY OF EPIDEMIOLOGY, SOCIOLOGY AND GENESIS OF UTERINE CERVICAL CANCER

J.E. MacGregor, University of Aberdeen, Dept. of Pathology, *Aberdeen AB9 1AS, Scotland, United Kingdom* (D-IARC-79-562)

The northeast area of Scotland is an ideal area for epidemiological studies being centred round one main city, Aberdeen. It is possible to identify individual women screened no matter how many cervical smears they have, how many different clinics they attend or how often they move within the area. Already a very high percentage of women in the region have had one or more cervical smears. A fall in the incidence of the disease has occurred and is continuing. A marked fall in mortality rates has occurred. There have been no deaths in women under 35 years of age since 1973 during which time the death rates in England and Wales were rising. Studies continue, with special emphasis on the genesis of this disease in young women.

EPIDEMIOLOGICAL AND CYTOPATHOLOGICAL STUDY AMONG NATAL BETHEL-CHEWING INDIANS WITH SPECIAL REFERENCE TO SUBMUCOUS FIBROSIS

J.D. Randeria, University of Durban Westville, Cancer Research Inst., *Private Bag X54001, Durban 4000, Natal, South Africa* (D-IARC-79-479)

Oral submucous fibrosis has been reported almost exclusively among Indians, especially betel/tobacco chewers. The lesion is believed to be precancerous. Qualitative and quantitative studies are being made of the Papanicolau-stained buccal smears. Epidemiological data are collected in a questionnaire at interview. Partial results of the study have been published (Proc. VI Perugia Quadrennial International Conference on Cancer. Perguia, June 1977).

ROYAL NAVAL DOCKYARDS ASBESTOSIS STUDY - MORTALITY PROJECT

C.E. Rossiter, Medical Research Council, Pneumoconiosis Unit, *c/o Llandough Hospital, Penarth CF6 1XW, Wales, United Kingdom* (D-IARC-79-682)

The 40,000 people working in the Royal Naval Dockyards in 1972/73 are being followed to relate their mortality, including mortality from lung cancer and mesothelioma, to history of asbestos exposure. The 7,000 men working in Devonport Dockyard on 1.1.1947 are also being followed to provide earlier indications of the effects of asbestos exposure on mortality. A group of 400 men heavily exposed to

asbestos are being followed up to relate mortality to indices of health measured in 1968.

FREQUENCY AND TREATMENT OF MYCOSIS FUNGOIDES AND PREMYCOTIC ERUPTIONS

P.D. Samman, University of London, Westminster Medical School, Westminster Hospital, *Page St., London SW1, England, United Kingdom* (D-IARC-78-585)

The objective of the study is to sort out the conditions which may progress to a cutaneous reticulosis and to differentiate them from similar benign conditions; to ascertain the frequency of these conditions (the majority are from the Greater London area, but the investigators also visit a number of other areas in England to collect suitable cases); and to determine the most suitable treatment.

HEALTH ASPECTS OF RE-USE OF WASTE WATER FOR HUMAN CONSUMPTION

A.G. Shaper, University of London, Royal Free Hospital School of Medicine, Dept. of Clinical Epidemiology & Social Medicine, *8 Hunter St., London WC1N 1BP, England, United Kingdom* (D-IARC-79-644)

The objectives of the research programme are to determine whether there is any relationship between mortality and morbidity from chronic diseases and the degree of contamination with sewage effluent of the source from which a community draws its drinking water supply. The programme involves an epidemiological study forming part of a project being coordinated and partly undertaken by the Water Research Centre. The study involves towns in the U.K. with populations greater than 50,000 in 1965-74. The hypothesis linking cancer mortality and site-specific cancers (gastrointestinal, urinary and others) with the proportion of the population drinking re-used water (as reported from Mississippi) will be examined for the United Kingdom. Other disease outcomes will be investigated to provide a basis for formulating further hypotheses.

CASE-CONTROL STUDY OF CERTAIN CANCERS AND EXPOSURE TO VARIOUS INDUSTRIAL ACTIVITIES IN A TOWN

A. Sjoeberg, Boliden Aktiebolag, Chemicals Division, *25100 Helsingborg, Sweden* (D-IARC-79-503)

Many malignant diseases have a far higher urban than rural incidence. Possible associations between the incidence of certain cancers and exposure to various industrial activities will be investigated and the proportion of morbidity attributable to such industrial sources elucidated. All cancer cases recorded for the town of Helsingborg (population about 80,000) in the Swedish National Cancer Register for the years 1958 to 1971 will be used for a case-control study. Two controls will be sought for each case with respect to sex, age and place of abode. Exposure is defined as previous occupation in some factory or factories or other defined activity. Employment rolls from, for example, inorganic chemical works, a rubber factory, a pharmaceutical laboratory, a shipyard or the local hospital will be studied. The exposure criteria will be as specific as possible. Resident industrial medical officers will cooperate in the project.

CORRELATIONS BETWEEN MORPHOLOGY AND EPIDEMIOLOGY OF BREAST CANCER

B.C. Stenkvist, University Hospital, Dept. of Clinical Cytology, *75014 Uppsala, Sweden* (D-IARC-79-527)

Within a clearly defined area and population (four Swedish counties) 181 breast cancer cases occurred during five months. For 179 of these patients epidemiological and morphological data were obtained. Epidemiological data were recorded in the same way for 179 exactly age-matched controls. Tumors were also characterized by computerized nuclear morphometry (CNM) of the cell populations in addition to conventional morphology, resulting in an objective measure of atypia, the CNM value. Conventional histopathological classification resulted in the definition of six subgroups: 62% in a 'not otherwise specified' category, 17% low differentiation (Ackerman group IV), 7% lobular, 5% mucinous, 3% papillary, 2% medullary and the rest inoperable cases (2%) or 'rare tumors' (4%). Patient-control comparison showed no significant difference in age at menarche, first birth or menopause, number of children, height, weight, obesity or frequency of diabetes or hypertension. These results differ from most earlier reports, possibly because controls were selected from the whole female population, not hospitalized patients. A family history of cancer and earlier breast disease was significantly more frequent in the patient group. Thyroid hormone level patterns suggested that the altered thyroid function in the patients was most likely due to a change in the peripheral conversion of thyroxine. Patients also had higher serum concentrations of oestrone, androstenedione and testosterone and a lower level of sex-hormone-binding globulin. No obvious differences in the epidemiological characteristics could be discerned between different conventional morphological subgroups. The CNM value was positively correlated to other biological parameters such as mitotic rate in the tumor. It also has a significantly higher reproducibility than subjective systems for classification or grading of breast cancer. Patients undergoing treatment with heart glucosides had a lower CNM value than the others.

AN INVESTIGATION INTO THE SO-CALLED PREMALIGNANT LESIONS OF THE ORAL CAVITY

C.W. van Wyk, University of Stellenbosch, Faculty of Dentistry, Dept. of Oral Pathology, *Private Bag 11, Tygerberg 7505, Cape Province, South Africa* (D-IARC-79-491)

The object of the study is to determine the prevalence, the anatomical distribution, the histopathology, the ultrastructure and histochemistry of the so-called premalignant oral lesions (leukoplakias) among different population groups in Cape province (Bantu, colored, white and Asian) paying due regard to habits, social circumstances and geographical distribution. Furthermore, a similar demographic study is being carried out on oral squamous carcinomas among the same people to make comparisons between the premalignant and malignant lesions possible. In addition all other oral mucosal lesions detected during the survey are recorded and their distribution plotted. Specific investigations are undertaken into the etiology of some, especially the atrophic lesions and lesions caused by viral infections.

CASE-CONTROL STUDY OF THE POSSIBLE RELATIONSHIP BETWEEN ORAL CONTRACEPTIVES AND CANCERS OF THE BREAST, ENDOMETRIUM AND OVARY

M.P. Vessey, University of Oxford, Social & Community Medicine, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom* (D-IARC-79-679)

Although a great deal is known about the short- and medium-term hazards of oral contraceptives, there is still a great need to monitor possible carcinogenic effects. In this investigation, women of childbearing age newly presenting with cancers of the reproductive system at any of six London teaching hospitals are interviewed, together with matched controls. The study has been in progress for about seven years and now includes nearly 800 cases of cancer of the breast. Preliminary results concerning the first 90 cases of breast cancer were published in the British Medical Journal in September 1972 and concerning the next 232 cases in the Lancet in April 1975.

THE DETERMINATION OF HIGH RISK GROUPS FOR BREAST CANCER SCREENING

B.A. Thomas, Midhurst Medical Research Inst., *Midhurst, Sussex, United Kingdom* (D-IARC-79-660)

Women aged 35 and over who have a family history of breast cancer and/or have had no viable pregnancy before that age, and/or have had a previous breast biopsy or cyst aspiration and/or in whom clinical examination is equivocal or difficult in view of nodular breasts are being screened by clinical examination with emphasis on minimal signs and mammography. Women with a clinical abnormality have the standard lateral and cephalocaudal mammographic views; the 'normal' women have single view only with breast compressed in a plane from the axilla to the xiphisternum giving a 45 degree oblique view with excellent visualization of the breast and a radiation exposure of around 0-18 rad. Detection rates are being compared with those from the screening of a similar group of women in Guildford, but using standard mammographic views for all women. To date the cancer rate in asymptomatic women is the same in the two groups. Epidemiological, clinical and mammographic risk factors are being studied.

STUDY OF CANCER OF THE LUNG AND STOMACH, AND OF BRONCHITIS MORTALITY IN RELATION TO URBAN FACTORS

R.E. Waller, Medical Research Council, *Fulham Rd., c/o Royal Marsden Hospital, London SW3 6JJ, England, United Kingdom* (D-IARC-79-649)

This is a study based on published mortality data. One of the features of the distribution of lung cancer deaths in recent decades has been the relatively high rate in urban areas, but the pattern is changing gradually and the death rates currently experienced by recent cohorts are not much higher in urban than in rural areas, a change most marked in London. These findings are being considered in relation to the substantial changes in pollution by smoke, as well as changes in smoking habits, and possible biases introduced by selective migration. The data have been accumulated gradually, as they become available, starting with deaths in 1951, and the object is to assess the trends over a 25 year period, arranged on a cohort basis. Data from this study for the Greater London area are also being used in connection with an investigation of lung cancer incidence among London Transport workers, over a similar 25 year period. The experience of the London Transport group as a whole is being compared with

that of the general population, and incidence rates are being calculated for several job categories with a view to exploring the effects of exposure to diesel fumes.

HORMONAL FACTORS IN THE ETIOLOGY OF BREAST CANCER
D.Y. Wang, Imperial Cancer Research Fund, Dept. of Clinical Endocrinology, *Lincolns Inn Field, c/o St. Bartholomew Hospital, London WC2A 3PX, England, United Kingdom* (D-IARC-79-650)
Results of a prospective study of the island of Guernsey, obtained in this laboratory, have shown that women who subsequently develop breast cancer have, on the average, a subnormal excretion of urinary androgen metabolites. The investigation now in progress is to examine (1) whether in a prospective study this urinary abnormality is reflected in the general circulating levels of plasma androgens, (2) plasma androgen levels in women with increased risk of breast cancer (e.g., race, familial history, age at first birth, etc.) and (3) the general androgen status in women with established breast cancer.

2.1534,
LONG-TERM FOLLOW-UP OF CHILDHOOD CANCER SURVIVORS
G.J. Draper, University of Oxford, Dept. of the Regius Professor of Medicine, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom* (D-IARC-79-674)
There is considerable concern about possible long-term effects of radiotherapy and chemotherapy used in treating children with cancer including the induction of second primary tumors. It has also been suggested, though at present direct evidence is lacking, that improvements in survival for certain categories of tumor, and the subsequent increase in the number of children born to survivors, will lead to the recognition that there is a genetic component in the aetiology of some of the cancers of childhood comparable to that for retinoblastoma. The Childhood Cancer Research Group is coordinating a collaborative study which will eventually include records of about 6,000 children who have been treated for cancer and survived for at least three years. These survivors will be followed up to determine the incidence of second tumors and also the incidence of abortions, stillbirths, congenital defects and malignant disease among their children. For children treated in Scotland, subsequent hospital admissions, school health records and other medical records are being studied and compared with corresponding records for a sample of controls, using record linkage. Various other long-term effects may be studied for cases from particular centres. It is planned also: (1) To carry out laboratory studies including hematological studies, cytogenetics and possibly measurement of immunoglobulins for some of the cases included in the study and (2) to establish a pathology registry for children in whom second primary tumors occur.

THE GENETICS AND EPIDEMIOLOGY OF RETINOBLASTOMA
G.J. Draper, University of Oxford, Dept. of the Regius Professor of Medicine, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom* (D-IARC-79-673)
The objectives of this study are: (1) To determine the incidence of second primary tumors, particularly osteosarcoma, among children surviving retinoblastoma; (2) to determine whether there is an increased incidence of other cancers, either in general or of certain specific types, among the parents of children with retinoblastoma; (3) to ascertain whether, as for certain congenital defects, the incidence of this disease is related to parental age; and (4) to examine associations between congenital defect, particularly mental retardation, and retinoblastoma. About 500 case of retinoblastoma have been ascertained through hospital, cancer registries and death certificates; epidemiological and familial data are also being collected.

CHILDHOOD CANCER REGISTRY
G.J. Draper, University of Oxford, Dept. of the Regius Professor of Medicine, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom* (D-IARC-79-672)
A registry for childhood neoplasms occurring in England, Scotland and Wales has been established with the following objectives: (1) To obtain estimates of incidence, mortality and survival rates, (2) to provide a basis for epidemiological, genetic and medical care studies, (3) to provide a service to other research workers. Registrations of cancer in children below age 15 and deaths below age 16 are reported to the Childhood Cancer Research Group by the Office of Population Censuses and Surveys, the Information Services Division of the Scottish Health Service, regional cancer registries, and clinicians. This is supplemented by clinical information derived from hospitals and general practitioner records. A classification system particularly appropriate for childhood cancer and based on the International Classification of Diseases for Oncology has been developed. Comprehensive data on incidence, mortality and survival have been analyzed and will be published by the Office of Population Censuses and Surveys. Studies currently in progress include: (1) Comparisons of survival rates for children with leukemia and Wilms' tumor included in MRC clinical trials with those for children not included, (2) the provision of treatment for children with cancer, (3) studies to determine whether there is an increased incidence of cancer in the parents of children with cancer.

PROLONGED AND VARIABLE EXPOSURE TO ASBESTOS FIBER
J.C. Cochrane, South African Medical Research Council, National Research Inst. for Occupational Diseases, Dept. of Occupational Medicine, *Joubert St. Ext., Johannesburg 2001, Transvaal, South Africa* (D-IARC-79-480)
Ninety-two senior staff members of a large asbestos/cement company with factories spread over the country are being studied. This company manufactures asbestos/cement products, roof and ceiling sheets, insulation boards, piping and moulded goods and the staff have been exposed to all of these as well as to visits to asbestos mines. Exposure has been estimated as heavy in 17, moderate in 23 and light in 52 persons. Medical examination, including X-ray, carried out in 1973, 1974 and 1976 revealed pleural thickening in 43 and thickening with parenchymal change in 3 persons. Follow-up of the cohort continues.

RETROSPECTIVE STUDY OF RISK FACTORS FOR CANCER, 1968-1978
M.D. Djordjevic, Inst. Ksenofon Sahovic, Cancer Epidemiology, *Pasterova 14, 11000 Belgrade, Yugoslavia* (D-IARC-78-1019)
Breast cancer ranks third in the mortality rates in the Republic of Serbia and the city of Belgrade. Hormone risk factors are being examined by retrospective and prospective study of patients seen at this Institute during the period 1968-1978: (1) Hormone

dysfunction as a risk factor in the development of breast cancer - prospective study. These investigations include inteview and estimation of 17-ketosteroids with histopathological verification of each case. (2) Selected variables such as menopause, menstruation, deliveries, abortions, number of children, lactation, marriage, occupation, blood group -retrospective study. (3) The role of socioeconomic status in the development of breast cancer. (4) Comparison of breast cancer frequency in the subregions of Serbia and Belgrade and monitoring of mortality statistics in Serbia and Belgrade.

OESOPHAGEAL CANCER STUDIES IN THE CASPIAN LITTORAL OF IRAN - RESEARCH IN AREAS OF EXTREME DIFFERENCES IN RISK

J. Kmet, University of Tehran, Inst. of Public Health Research, *Tehran, Iran* (D-IARC-79-287)
Work is in progress for detailed studies of the interplay between malnutrition, specific organ and tissue susceptibility and repair and immune response in well defined high and low risk groups. Population genetic patterns will be assessed as well as immunogenetic background. The possible effect on oesophageal tissues of opium tar, an exposure widespread in this and other parts of the country, will be examined. Food is being investigated for fungal contamination and the significance of extraneous seeds in wheat assessed. Post mortem tissue from high incidence areas is being examined and endoscopy offered to a high risk population.

SHORT-TERM VARIATION IN PRE-NATAL CANCER RISK

J.F. Bithell, University of Oxford, Dept. of Biomathematics, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom* (D-IARC-79-667)
An analysis has been undertaken in which all deaths from malignant disease of British children between 1953 and 1971 have been tabulated by month of birth and age at death. Comparative 'expected' numbers have been computed with allowance for survey coverage, cohort size and secular trends. A program has been developed which is designed to correlate these series of observed and expected numbers in an appropriate manner with any time-varying factor of interest. A study of the temporal association with influenza and poliomyelitis incidence has been completed; the data are available for the analysis of any monthly observations that may be of etiological interest or significance.

CANCER MORTALITY IN 11,121 MALES BORN 1903-1928 - A COMPONENT OF A YUGOSLAVIAN CARDIOVASCULAR DISEASE STUDY (ABBREV)

D. Kozarevic, Inst. of Chronic Diseases & Gerontology, Dept. of Chronic Diseases, *Slobodana Penezica 35/2, Belgrade, Yugoslavia* (D-IARC-79-1087)
The Yugoslavia Cardiovascular Disease (CD) study was initiated in 1961-1963 in two geographical areas in Yugoslavia (Tuzla and Remetinec). The study population comprised 11,121 males, both urban and rural residents, aged 35-64 at the initial examination in 1964. This population was subsequently re-examined by the same study teams on two occasions, the last time seven years following the initial examination. The methodology and results were compared with those of the Framingham Study, USA (J. Chron. Dis., 29:405-411, 1976 and Am. J. Epidem., 104, 133-140, 1976). Mortality follow-up for the cohort is essentially complete. The centralized mortality register makes it possible, in principle, to identify the death of any specific person occurring within the country. The re-examination of the cohort provided means to check the completeness of this mortality follow-up and update the mortality lists. There is a distinct excess of cancer mortality in the Yugoslavian study population, the age-adjusted rate being 60% higher than in Framingham. The most striking excess is for stomach cancer which accounts for a vastly greater proportion of cancer deaths in Yugoslavia (23.2%) than in Framingham (3.7%). As in other populations, this excess appears to be accompanied by a lower mortality from cancer of the large intestine. If the age-adjusted mortality for cancer is expressed as a percentage of the total age-adjusted mortality, Framingham and United States mortality are very similar whereas cancer mortality in the Yugoslavian study areas is higher than in the country as a whole. There is a strong likelihood that the Yugoslavian CVD study areas have higher than the average cancer mortality for the country. These findings are being further investigated.

BRITISH RUBBER MANUFACTURERS' ASSOCIATION HEALTH RESEARCH PROJECT

H.G. Parkes, Regional Cancer Registry, *c/o Queen Elizabeth Med. Ctr., Birminghan B15 2TH, England, United Kingdom* (D-IARC-79-571)
The aim of this study is to examine the health records of workers in the British rubber industry and to compare their mortality experience with that of the general population. All major type companies are included, together with some associated products. The study also compares the experience of three distinct cohorts of entry to the industry - first for those who entered the study between 1946 and 1950, the second between 1951 and 1955, and the third between 1956 and 1960. Although the main aim of the study is to investigate possible excesses of cancer hazards, all causes of death are recorded and certain other groups of causes are being examined. It is hoped to be able to associate any high risk areas with the results of environmental monitoring tests that have been made in the last year or so and with such details as can be obtained of past conditions in each factory. Analysis of the results to date has shown a small, but significant, excess of malignant disease of the stomach and of the lung, particularly in recent entry cohorts. Except for the first entry cohort there is no raised incidence of bladder cancer. This is in line with the banning of the use of 2-naphthylamine in 1949. Detailed studies of the conditions of work in those areas which show an excess of malignant disease in each factory are now being made and a further follow-up of mortality records is being undertaken.

SCREENING PROGRAM FOR AN EARLY DIAGNOSIS OF PRIMARY CARCINOMA OF THE LIVER - INVESTIGATION OF INCIDENCE RATES OF PLC AND LIVER CIRRHOSIS

W. Weiss, Krankenanstalt Rudolfstiftung, Dept. of Medicine, *Juchgasse 25, A1030 Vienna, Austria*
OBJECTIVE: Strengthening of our hypothesis that primary liver carcinoma (PLC) ranges among the ten most frequent malignant tumor diseases in Austria.
APPROACH: Prospective study (6 years) to improve the clinical significance of our screening program for obtaining early diagnosis of PLC (alpha-1-fetoprotein (AFP) determination in the serum, two-step liver scintigraphy with 99m-Tc-S-colloid and 67-gallium citrate).
Investigation of the importance of hepatitis-B antigen in the pathogenesis of PLC in Austria.
PROGRESS: Our study started in Jan. 1973, and is planned prospectively to last until Jan. 1979. During the first 4 years we registered 108 patients with PLC in our hospital. Intra vitam diagnostic efficiency increased from 34% to 85%.

NON-HODGKIN'S LYMPHOMAS IN CHILDREN

L.I. Schwartz, Hospital de Ninos de Buenos Aires, Dept. of Pathology, *Gallo 1330, 1425 Buenos Aires, Capital Fed, Argentina* (D-IARC-79-4)
From 1965 to 1977 a total of 140 children with non-Hodgkin's lymphomas attended the Oncology Unit of the Children's Hospital de Buenos Aires. A male preponderance was found and the peak age was five years. The most frequent location was the abdomen, in particular the ileocaecal region. The histological pattern in a high percentage of cases was the diffuse poorly differentiated lymphocytic form. The main objectives of future epidemiological research will be detection of primary immunodeficiency disorders and evaluation of the frequency of herpes and/or other virus infections.

TIME TRENDS IN ALCOHOL CONSUMPTION AND ALIMENTARY TRACT CANCER MORTALITY IN AUSTRALIA

A.J. McMichael, Commonwealth Scientific & Industrial Research Org., Div. of Human Nutrition, *Kintore Ave., Adelaide, S. Australia 5000, Australia* (D-IARC-79-7)
Australia has a high consumption of alcoholic drinks, by international standards. Further, there has been considerable variation, both in amount and type of drink, during this century. By analysis of sex-age-specific time trends in cancer mortality in this century, in the light of consumption time trends for alcohol and cigarettes, the aetiological contribution of these two factors is being assessed for cancers of the oropharynx, oesophagus, colon, rectum and, particularly, the larynx. Specific attention is being paid to cohort analysis of the data. Case-control studies for cancers of the large bowel and the larynx are now being planned. The large Greek migrant population in Australia holds promise for case-control studies of cancer of the rectum, in view of the low incidence rates reported for Greece.

2.1552,

EPIDEMIOLOGICAL STUDY OF CANCER IN ALGERIA 1946-1955 AND 1966-1975

A. Yaker, Centre Hospitalo Universitaire Mustapha, Laboratoire Central dAnatomie Pathologique et de Cytologie, *Algiers, Algeria* (D-IARC-79-1)
Data on histologically diagnosed cases of cancer are collected from pathology laboratories in Algiers, Oran and Constantine which cover the whole country. This includes: histopathological diagnosis; site; age; sex; ethnic group and geographical distribution. The relative frequency will be studied for two ten-year periods. If feasible, minimum incidence rates will be calculated and high risk groups determined as part of planning for a national program of cancer control.

RELATIONSHIP BETWEEN BRACKEN INFESTATION AND CANCER MORTALITY IN VICTORIA, AUSTRALIA

R.K. Scragg, Commonwealth Scientific & Industrial Research Org., Div. of Human Nutrition, *Kintore Ave., Adelaide, S. Australia 5000, Australia* (D-IARC-79-9)
Rural Victoria has areas of bracken fern infestation. The mortality from all types of cancer is being compared between the populations living in bracken and non-bracken areas. Prior epidemiological and experimental research has indicated an increased risk of bladder cancer and bowel cancer in association with the ingestion of bracken fern.

RELATIONSHIP BETWEEN LEVELS OF NITRATE IN DRINKING WATER AND CANCER MORTALITY

R.K. Scragg, Commonwealth Scientific & Industrial Research Org., Div. of Human Nutrition, Division of Human Nutition, *Kintore Ave., Adelaide, S. Australia 5000, Australia* (D-IARC-79-10)
Environmental nitrates in water, by their bacterial conversion to nitrosamines, are thought to be associ-

ated with an increased mortality from cancer, especially stomach cancer. The Southeast of Australia, in particular the State of Victoria, has communities with high levels of nitrate in their drinking water. The type-specific mortality rates for all cancers are being compared in the high and low water nitrate areas of rural Victoria.

INCIDENCE OF CANCER IN WESTERN AUSTRALIA

M.M. Lugg, University of Western Australia, *Perth, W. Australia 6009, Australia* (D-IARC-79-28)
Western Australia has a diverse climate over its 1,000,000 square miles of area, and a scattered population of approximately 1,000,000. This population has remained relatively stable, making possible extensive epidemiological analysis, including long term follow-up. Cancer incidence, by site, age, sex, geographic location of patient, work history, and detailed treatment for three months following diagnosis is currently being analyzed.

THE EVALUATION OF CENTRAL CANCER REGISTER BASED UPON HOSPITAL, DEATH AND PATHOLOGY STATISTICAL SYSTEMS

M.M. Lugg, University of Western Australia, Dept. of Public Health, *Perth, W. Australia 6009, Australia* (D-IARC-79-29)
Western Australia has a diverse climate over its 1,000,000 square miles of area, and a scattered population of approximately 1,000,000. This population has remained relatively stable, making possible extensive epidemiological analyses, including long term follow-up. The present cancer register uses as data sources hospital discharge summaries, death registrations, pathology reports and radiotherapy attendances for locating patients with cancer. The current study attempts to define how complete the 'case finding' is using these methods.

CARCINOMAS OF THE URINARY TRACT AND ASSOCIATION WITH ANALGESIC ABUSE

G. Duggin, Royal Prince Alfred Hospital, Renal Unit, *Missenden Rd., Camperdown, Sydney, N.S.W. 2050, Australia* (D-IARC-79-32)
The aim of the study is to determine the incidence of carcinomas of the urinary tract in patients who abuse analgesics, particularly those containing aspirin, phenacetin, caffeine, paracetamol and salicylamide. Patients studied will be those referred to Royal Prince Alfred Hospital with analgesic-induced renal disease (analgesic nephropathy) or those patients known to abuse analgesics. This group of patients will be followed prospectively to determine the frequency and type of carcinomas of the urinary tract and which analgesic is specifically associated with the development of these carcinomas. It is anticipated that between 50 and 400 such persons will be followed. Controls will be age- and sex-matched patients with comparable renal disease, who do not consume analgesics, attending the same clinic.

DYSPLASIA OF THE UTERINE CERVIX

V.F. Oliveira, Ministerio da Saude, Gynecol. Cancer Prev. Service, *295 V. Barcelona, Sao Paulo 09500, Sao Paulo, Brazil* (D-IARC-78-56)
This study of dysplasia of the uterine cervix is based on a follow-up for a period of seven years (1970-1977). Participants were recruited on the basis of cytological results of suspicious malignancy (Papanicolaou Grade III) or biopsy evidence of dysplasia. Associations between dysplasia and skin color, age, onset and frequency of sexual activity, parturition, and type of contraceptives employed and period of use are being examined. The effect of treatment is also being examined.

THYROID CANCER AND ENDEMIC GOITER

G. Riccabona, Leopold Franzens Universitat Innsbruck, *Innrain 52, 2 6 Universitatsstrasse, A6020 Innsbruck, Austria* (D-IARC-79-38)
For decades a possible correlation between endemic goiter and thyroid cancer has been discussed. So far only contradictory evidence has been obtained, perhaps due to the fact that epidemiological data from endemic goitre areas in developing countries are insufficient. The present study includes epidemiological data from western Austria (about 90 percent of thyroid cancer cases from this area seen in this department) where extensive studies on the incidence of endemic goiter have also been carried out. These figures will be compared with relevant data from other countries all over the world.

KIDNEY CANCER AND TOBACCO CONSUMPTION

C. Vutuc, Universitat Wien, Inst. of Hygiene Social Medicine & Epidemiology, Sozialmedizin & Epidemiologie, *Kinderspitalgasse 15, 1095 Vienna, Austria* (D-IARC-79-40)
The aim of this retrospective survey is to determine if smoking causes kidney cancer. The emphasis will be on cancers of the renal pelvis - about 150 such cases will be studied - although cancers of the renal parenchyma will also be included. For each case two matched controls with non-tobacco selected disease will be interviewed. The results of tobacco smoking in both cases and controls will be compared with data from the Austrian population collected in 1972 and 1977.

UTERINE CANCER - COMPARATIVE STUDY OF URBAN AND RURAL WOMEN

J.C. Machado, Instituto Brasileira de Cont. Cancer, *Av. Alcantara Machado, Sao Paulo 2576, Sao Paulo, Brazil* (D-IARC-79-54)
The Instituto Brasileiro de Controle do Cancer (IBCC) in collaboration with Fundacao Centro de Pesquisa de Oncologia (FCPO) undertakes a programme for uterine cancer detection and prevention in large female population. Cytological tests are made on all women registered in the programme. Colposcopy and biopsy follow if dysplasia or carcinoma are detected on the first screening. Participants are interviewed and information on socioeconomic status, age, number of children, etc. is collected. The main objective is to make a comparative study of the prevalence of and conditions that contribute to uterine cancer in urban and rural women.

INCIDENCE OF BREAST CANCER IN CANADIAN INDIANS AND ESKIMOS CORRELATED WITH THEIR CHANGING LIFE-STYLES

M.S. Beare, Canadian Dept. of National Health & Welfare, Medical Services Branch, *401 Toronto Dominion Tower, Edmonton Centre, Edmonton, Alberta, Canada* (D-IARC-79-60)
Cancer of the breast was considered to be unknown in Canadian Indians and Eskimos 25 years ago. It is still rare in Eskimos but is fairly common in Indians, though probably less common than in the general Canadian population. The question of whether there has been a real change in incidence is being studied, and, if so, whether the change is associated with the marked changes in life-style of the native people in recent years. Of particular interest is whether prolonged breast feeding (of about two years) can be shown to have protected women from breast cancer. Diet is also being examined.

CHILDHOOD CANCER REGISTRY AND INVESTIGATION OF THE AETIOLOGY OF CHILDHOOD CANCERS

M.G. Grace, Dr. W.W. Cross Cancer Inst., Biostat Anal & Cancer Registry, *11560 University Ave., Edmonton, Alberta, Canada* T6G 1Z2 (D-IARC-78-67)
A childhood cancer registry will be established to include all children (persons aged less than 20 at the time of diagnosis) in the Alberta Cancer Registry. Information will be collected, whenever possible directly from the patient or family, on the family history of cancer, other diseases, places of residence and schooling, and exposure of parents and child to drugs or noxious chemicals. This data will be compared with information available for the whole province and analyzed for any relationship between these factors and total cancer incidence or cancer of particular sites or types.

2.1567,

GEOGRAPHICAL DISTRIBUTION OF MALIGNANT NEOPLASMS OF THE BRAIN IN CANADA

I.C. Neutel, University of Ottawa, Faculty of Medicine, Dept. of Epidemiology & Community Medicine, *1145 Carling Ave., Lady Grey Bldg., Ottawa, Ontario, Canada* K1Z 7K4 (D-IARC-79-85)
Malignant neoplasms of the brain have received very little epidemiological attention in spite of the low survival rate and their occurrence in childhood or early adulthood. A few studies dealt with their general distribution in the United States and Denmark and only one studied the geographical distribution in relation to environmental factors. This project will study the geographical distribution of brain tumours across Canada using both mortality and incidence data by calculating age-adjusted mortality and incidence rates for census divisions. These rates can be related to various environmental variables known for the census divisions. In addition, this study will investigate the occupations recorded for a select group of brain tumour deaths and compare them with a matched group of controls. Of special interest will be occupations likely to involve chemical or radiation exposure. Prenatal radiation has been shown to increase the risk of childhood cancer of the central

nervous system, and the same situation may apply to adult brain cancer.

INDUCIBILITY OF ARYL HYDROCARBON HYDROXYLASE IN CULTURED LYMPHOCYTES FROM LUNG CANCER PATIENTS AND CONTROLS
W. Kalow, University of Toronto, Dept. of Pharmacology, *92 College St., Toronto, Ontario, Canada* M5S 1B2 (D-IARC-79-100)
The overall objective of this study is to assess the potential usefulness of the lymphocyte aryl hydroxylase test as a tool for epidemiological studies on genetic susceptibility to chemical carcinogens. The activity and inducibility of AHH in lymphocytes vary widely between subjects. Kellermann and co-workers (1973) suggested a higher susceptibility to lung cancer, caused by carcinogens in cigarette smoke, in subjects with higher inducibility of this enzyme. Since the inducibility of AHH is genetically controlled, some subjects appeared to be genetically predisposed to this type of cancer. However, the test determining the AHH inducibility in lymphocytes was never applied in preventive medicine; there has been criticism of the reproducibility of the method and the implications of the results. Nevertheless, as several recent papers supported a relationship between agents, patients with lung and other types of cancer and healthy volunteers are being studied in respect of the distribution of AHH inducibility. The method is being improved to make it more suitable for testing cancer patients.

CASE-CONTROL STUDY OF AETIOLOGICAL FACTORS IN HEAD AND NECK CANCER
J.M. Elwood, Cancer Control Agency of British Columbia, Epidemiology Unit, *2656 Heather St., Vancouver, British Columbia, Canada* V5Z 3J3 (D-IARC-79-110)
The objective of the study is to evaluate the association of alcohol, tobacco and occupation to cancer of the head and neck, and to determine whether such exposures are independent or interactive. It is planned to interview all new patients with these tumors seen at the Cancer Control Agency of British Columbia (which includes about 90 percent of new cases in the province) over a 3 1/2 year period, to give a total of about 350 cases. The control group will consist of an age-and sex-matched group of patients with other tumors chosen on the basis of lack of association with the main exposures, for example breast and gynecological cancer in women, chronic lymphomas and multiple myeloma, and prostatic tumors in men. The interview will provide information on a lifetime occupational history and quantification of current and past tobacco and alcohol usage habits.

MALIGNANT LYMPHOMA IN COLOMBIA IN RELATION TO EPSTEIN-BARR VIRUS
A. Duenas Lehmann, Universidad del Valle, Dept. of Microbiology, *Apartado Aereo 2188, Cali, Colombia* (D-IARC-79-117)
The objective of this study is to explore the role of Epstein-Barr virus (EBV) in Hodgkin's disease and other malignant lymphomas in Colombia. Serum samples are obtained from patients and appropriate controls, and malignant lymph nodes from biopsy or autopsy. The samples are immediately frozen and stored in low temperatures for periodic shipment to laboratories in the United States for detection of viral markers in both serum and tissues. There is as yet no indication of an association between EBV infection and malignant lymphoma in Colombia, but at least 50 cases will have to be examined before any conclusion can be drawn.

2.1573,
LUNG CANCER IN CUBAN WOMEN
O. Joly, Instituto de Oncologia y Radiobiologia, *Calle 29 y E Vedado, Havana 4, Cuba* (D-IARC-79-120)
The objective of this restrospective study is to document lung cancer incidence among Cuban women as a function of smoking habits and other life-style factors. The mortality rate for women living in Cuba is one of the highest in the Western hemisphere. The study incorporates a case-control design, using a neighborhood and hospital control for each lung cancer case. Data will be obtained for types of tobacco used, number of years of smoking, pattern of smoking, drinking habits and demographic information. Central data analyses will be performed at Enviro Control Inc., Rockville, Md. USA.

ENDOMETRIAL CARCINOMA
V. Ottis, Inst. for Postgraduate Medical Education, *Limbova 20, Bratislava 80946, Czechoslovakia* (D-IARC-78-110)
Fifty years ago cancer of the endometrium was rare in Slovakia, but has continuously increased since 1955. Previously cancer of the cervix uteri was the most common uterine cancer. At present the ratio of the cancer cervix/endometrium is 1.2:1. Fifty years ago Slovakia was not very industrialized, but during the past 30 years has become so, with all that follows, i.e., longer expectation of life, increased living standards, smaller families and an increasing use of hormone preparations. The relationship between the increase of endometrial cancer and the consequences of the changes in lifestyle enumerated above is being investigated.

GEOGRAPHICAL PATTERNS OF CANCERS IN SLOVAKIA
I. Plasko, Slovak Akademie Ved, Inst. of Experimental Oncology, Dept. of Epidemiology, *Ul. Csl. Armady 21, Bratislava 88032, Czechoslovakia* (D-IARC-79-122)
Geographical variations of cancer mortality and morbidity within Slovakia - the eastern part of Czechoslavakia - are being examined. Two five year periods 1968-1972 and 1973-1977 will be compared. The relation to the age, sex, rural, urban and/or industrial areas will be studied. The objective of this investigation will be to collect the basic data for the start of a population-based cancer registry, to evaluate the validity of cancer notification and to establish current geographical patterns of cancer mortality and morbidity as a basis for further analytical studies.
SUPPORTED BY (No Supporting Organization Reported) funds n.a.

2.1576,
GEOCHEMICAL ENVIRONMENT AND OCCURRENCE OF MALIGNANT TUMORS IN SELECTED DISTRICTS OF CZECHOSLOVAKIA
V. Jilek, Inst. of Mineral Raw Materials, Dept. of Technology, *Vitezna 425, Kutna Hora 28403, Czechoslovakia* (D-IARC-79-124)
The chemical composition and radioactivity of drinking waters in selected districts of Czechoslovakia are being studied in relation to the observed differences in the occurrence of malignant tumors. Maps will be made using the data obtained, the amounts of chemical elements ingested by the population calculated and the relation between the geochemical environment and mortality from malignant tumors evaluated statistically. The levels of some trace elements in selected organs of the human body (necropsy material) will be determined by neutron activation analysis and atomic absorption spectrophotometry.

MALIGNANT POTENTIAL OF ORAL LICHEN PLANUS
P. Holmstrup, University Hospital, Dept. of Oral Medicine & Oral Surgery, *Rigshospitalet, DK2100 Copenhagen, Denmark*
The objective of this study is to obtain information on the potential for malignant transformation of oral lichen planus lesions over a 15-year period. 700 patients with histologically verified oral lichen planus are being followed. The patients are asked about past and present oral symptoms and smoking habits. The location and type of oral lichen planus lesions are registered and photographed. After the first examination the patients are seen once a year, except those with epithelial dysplasias who are seen every three months. At the follow-up examinations all changes in the lesions are recorded, photographed and, if necessary, biopsied. So far, five patients have been found with a simultaneous occurrence of lichen planus and erythroplakia. The influence of smoking on the lesions will be studied.

2.1580,

AETIOLOGY AND PROGNOSIS OF PLEURAL CALCIFICATION

T.J. Partanen, Inst. of Occupational Health, Dept. of Epidemiology & Biometry, *Haartmaninkatu 1, SF00290 Helsinki 29, Finland* (D-IARC-79-150)

This project concerns the asbestos-related aetiology of pleural calcification and, from the standpoint of cancer, the prognosis of these calcifications. The study of prognosis has been directed mainly toward mortality from neoplasms in a cohort of 608 persons with pleural calcification and 608 persons without such calcification at the start of follow-up. The cohorts were formed in 1972 in connection with compulsory chest radiography of the populations of three communities: one with an anthophyllite mine and mill, another with an asbestos cement plant and a third 'average' urban community. Persons working in these two plants have been identified. The cohorts were matched by age and sex and were between 20 and 74 years of age at that time. By the end of 1976, 18 deaths from neoplasms were observed in the calcification group, and 14 in the reference cohort. For malignant neoplasms of the respiratory tract, the figures were 10 and 8 respectively, and for the neoplasms of the lymphatic and haematopoietic systems, 3 and 0. Follow-up will be extended for at least five more years.

EPIDEMIOLOGICAL STUDIES OF CANCER IN TWINS

I.V. Rantasalo, Helsingin Yliopisto, Dept. of Public Health Science, *Fabianinkatu 33, SF00290 Helsinki, Finland* (D-IARC-79-151)

The study of twins can illuminate the relative role of different environmental factors in cancer aetiology. The Finnish Twin Registry contains data on some 34,500 adult twins of the same sex. Zygosity was determined by questionnaire in 1975. Record linkage with the Finnish Cancer Registry for cancer incidence prior to 1975 has been carried out. Since data on zygosity for many of the cases in this retrospective study were not available, cancer incidence in twins and risk of cancer among co-twins of cancer cases was compared for twins vs. non-twins using 7,332 singletons as controls. The study will be continued for several years until there are enough cases available to provide data on zygosity. The work already carried out has been used as the basis of publications on this subject.

REGISTER OF WORKERS OCCUPATIONALLY EXPOSED TO TRICHLOROETHYLENE

S.A. Tola, Inst. of Occupational Health, Dept. of Epidemiology & Biometry, *Haartmaninkatu 1, SF00290 Helsinki 29, Finland* (D-IARC-79-156)

A cohort of 1,881 workers has been identified from the list of workers whose urinary trichloroacetic acid has been measured at the Institute of Occupational Health. The cancer mortality of this group will be studied. Since most of the workers are relatively young (70% less than 50 years old), a prospective follow-up study will be undertaken after registering the exposure level and current vital status of the workers. The data will be analyzed by comparing the observed cancer mortality rates to those expected, as calculated from the national figures. It is also possible to compare the mortality figures with those of other occupational cohorts which are registered at the Institute of Occupational Health (e.g., stone workers, foundry workers, workers exposed to styrene).

COMMUNITY EXPOSURES TO VINYL CHLORIDE MONOMER

R. Saracci, Centre International de Recherche sur le Cancer, Epidemiology & Biostatistics Unit, *150 Cours Albert Thomas, 69372 Lyon Cedex 2, France* (D-IARC-79-181)

A study is being undertaken of current (cross-sectional) mortality for the years 1947-1977 in the resident population of a town of 28,800 (1971) in which a large chemical factory is located. This factory has produced, among a variety of other chemicals, vinyl chloride monomer (VC) since about 1953 and discharge into the air occurs. Death certificates of residents are collected and coded (ICD-8) and a time trend analysis, by sex, age and cause of death, is being made in comparison with the corresponding time trends for the country as a whole. In addition, time trends of proportional mortality of age, sex, cause of death and residential history within the town are computed. In parallel, a historical prospective study of families of surviving past and present VC workers and a group of workers at the same chemical factory matched by age and present residence is being conducted. Reproductive history is assessed, with special attention being paid to abortions and malformations, by interview with wives (whenever possible).

TIME TRENDS OF PRIMARY LIVER CANCER FROM CANCER REGISTRY DATA

R. Saracci, Centre International de Recherche sur le Cancer, Epidemiol & Biostatistics Unit, *150 Cours Albert Thomas, 69372 Lyon Cedex 2, France* (D-IARC-78-170)

The objective of the study is to assess evolution in time of primary liver cancer on a global basis scale using data extracted from three volumes of 'Cancer Incidence in Five Continents'. Changes in incidence rates in the period 1958-1971 are tabulated together with changes in the proportion that primary liver cancer represents of all cancers, using standardized (world standard) rates for all ages and for the 0-44 age group, for males and females separately. Time comparisons are possible for 37 populations in 30 registries. A number of correlations are also being explored comparing changes in primary liver cancer incidence with the corresponding changes in mortality (whenever available), with gallbladder cancer incidence, with cirrhosis mortality, with alcohol consumption and income.

EVALUATION OF EARLY DETECTION OF CANCER OF THE CERVIX UTERI BY CYTOLOGICAL SCREENING

D. Neuser, Staedtisches Krankenhaus im Friedrichsham, Zytodiagnostisches Zentrallabor, *Leninallie 49, 1017 Berlin, German Democratic Republic* (D-IARC-79-197)

From 1955 to 1969 the situation with respect to cervical carcinoma in Berlin, the capital of the German Democratic Republic, has hardly changed, as morbidity and mortality as well as stage distribution and 5-year survival rate have remained much the same. It is proposed to test whether cytological screening can serve to lower morbidity and mortality. For this purpose, all women from the ages of 20 to 65 living in Berlin will be cytologically examined every two years. Using the National Central Cancer Registry, the relationship of carcinoma in situ to invasive carcinoma, the stage distribution of the invasive cervical carcinomas and morbidity and mortality before, during and after screening will be investigated. The first four years were characterized by a considerable increase of the carcinomas in situ and a shifting of stages in favor of stage Ia and Ib at a coverage rate of 80 percent of the target population.

GENETICS OF GASTRIC CARCINOMA

J.K. Lehtola, Oulu University Central Hospital, *Kajaanintie 51, 90220 Oulu 22, Finland* (D-IARC-79-160)

The occurrence of gastric carcinoma was evaluated in 2,242 first-degree relatives of 341 probands with gastric carcinoma diagnosed in Finland during 1962-1963 and in 2,301 control relatives of 341 probands, age- and sex-matched, from the general population. The results suggest that the occurrence of gastric carcinoma is higher in the series than in controls. The most apparent difference was with respect to relatives of probands with the diffuse type of gastric carcinoma in whom the occurrence of gastric carcinoma was significantly higher than in their controls. The families with the intestinal type of gastric carcinoma behaved like the controls. The study continues.

RISK FACTORS OF BREAST CANCER - SCREENING FOR BREAST CANCER

I.H. Soini, Pirkanmaa Cancer Society, Detection CTR & Laboratories, *Haemeenskatu 5 A, 33101 Tampere 10, Finland* (D-IARC-78-150)

All women aged 41-60 (20,644) living in the city of Tampere were invited to undergo a breast cancer screening during the period April 1974-March 1975. Epidemiological data concerning reproductive and hormonal risk factors of breast cancer were obtained at the same time. Evaluation of the effect of this screening program on breast cancer risk is being made through follow-up in the National Population Registries.

INTERNATIONAL HISTORICAL PROSPECTIVE STUDY OF HEALTH EFFECTS OF MAN-MADE MINERAL FIBRES IN THE PRODUCER INDUSTRY

R. Saracci, Centre International de Recherche sur le Cancer, Epidemiology & Biostatistics Unit, *150 Cours Albert Thomas, 69372 Lyon Cedex 2, France* (D-IARC-79-180)

The objective of the study is to determine the mortality experience and, whenever possible, the cancer incidence of workers in the man-made mineral fibre (MMMF) production industry. Starting in 1976, factories belonging to the European groups of MMMF manufacturers (CIRFS-EURIMA) were individually visited to identify plants suitable for a historical prospective study, according to the following criteria: (1) No loss or destruction of personnel records; (2) MMMF production process in operation for at least

twenty years; (3) some method of mortality/morbidity follow-up available; (4) nominal fibre-size of some fibres less than five microns. On this basis 13 plants, located in seven countries, were selected for study and data collection at these plants, in which workers exposed to MMMF total approximately 4,500, is starting in 1978. Environmental measurements of airborne MMMF concentrations are being carried out in parallel by a team from the Institute of Occupational Medicine, Edinburgh, U.K. Follow-up of the workers will be the responsibility of national collaborating institutions, and comparisons are to be made between groups of workers with various levels of exposure and between worker populations and general (national or regional) populations. All data will be finally submitted to a central, common analysis.

STUDY OF OCCUPATIONAL CANCERS

L. Horbach, Friedrich Alexander Universitat zu Erlangen Nurenberg, Institut fuer Medizinische Statistik und Dokumentation, *Waldstr. 6, D8520 Erlangen, Federal Republic of Germany* (D-IARC-79-206)

The aims of this study are: (1) to survey manual workers and other staff employed in chemical and related industries for cancer and (2) to analyze possible aetiological associations between different cancer sites and occupational chemical exposures. In this retrospective study of the years 1950-1968 all ill and/or deceased employees (active or retired) of 10 large firms have been included and for the same time period all other deaths from one of those firms also have been collected. Information has been collected on sex, cause of death, occupation, substance to which exposed and for the cases of cancer: type of neoplasm, age at time of diagnosis and method of diagnosis. For the statistical analysis a multivariate model is being used. In February 1979 a detailed description of the study (more than 400 pages) was presented; it should be discussed in several expert groups in April and in autumn 1979. The study will be published in 1980 in a research report of the DFG.

RELATION BETWEEN MEAT-CURING BY SMOKE AND FREQUENCY OF STOMACH CANCER

G. Hajdu, (No Performing Organization Reported), *Hungary* (D-IARC-79-240)

In this area (Wend) it is traditional to smoke pork with freshly cut soft woods (alder, together with the fruit of the juniper bush). In such meat the amount of 3,4-benzpyrene is six times higher than in factory-smoked samples and other cocarcinogens have been found in these products. The farmers of Wend eat three to four times more of this meat than the average Hungarian, as do the Wends living in Solvenia near the Hungarian border. The frequency of stomach cancer has hitherto been twice as high among the population of Wend as among other groups living around this area. An educational campaign is expected to lead to a decrease in the frequency of this cancer in Wend.

CASE-CONTROL STUDY OF BREAST CANCER

Z. Pentek, County Hospital, Dept. of Radiology, *Beri-Balogh Adam 7/23, 7100 Szekszard, Hungary* (D-IARC-79-253)

The aim of the investigation was to estabish the factors most frequently associated with breast cancer, one of the most common female malignancies. In two southern counties of Hungary, 562 breast cancer patients, both urban and rural, were investigated using a computer-adapted questionnaire. The study group consisted of 195 premenopausal, 135 menopausal and 232 postmenopausal women. Replies were compared with those from an age-matched control group selected from 8,000 women screened for breast cancer in the same geographical area. Preliminary analysis shows a twofold excess in breast patients of higher educational level (secondary school or more), blood relatives (mother and/or sister) suffering from breast cancer, nulliparae, first pregnancy after the age of 25, no suckling or feeding a baby from one breast only, menarche before the age of twelve, previous diseases such as struma and former breast operation.

AN INTERVENTION STUDY OF ORAL CANCER AND PRECANCEROUS LESIONS IN RELATION TO TOBACCO USE IN RURAL INDIAN POPULATIONS

F.S. Mehta, Tata Inst. of Fundamental Research, Basic Dental Research Unit, *Homi Bhabha Rd., Bombay 400005, Maharashtra, India* (D-IARC-79-267)

Through follow-up studies for the last ten years it has been established that tobacco usage in the various forms practiced in different parts of India is definitely associated with oral cancer and precancerous lesions. The incidence of precancerous lesions among those who do not use tobacco in any way was almost zero, whereas the incidence among those who do ranged from 1 to 35 per 1,000 per year, depending upon the form of usage. The next step is to determine whether the association between oral cancer and precancerous lesions and tobacco usage is direct by demonstrating a reduction in the incidence of precancerous lesions when the tobacco usage is discontinued. A sample of 12,000 individuals using tobacco has been examined and interviewed in each of the three rural areas under study. A concentrated program of education, motivation and guidance has been prepared to persuade these villagers to give up tobacco. The villagers are shown a documentary film, especially made for this purpose, in the vicinity of their homes, in the most suitable format formulated after conducting impact studies of the film in each of the three areas. The message is also communicated personally to each of the examined individuals. In addition, the population is subjected to visual, audio and other media support. These individuals are re-examined annually to assess changes in tobacco usage habits, development of new oral precancerous lesions and changes in previously diagnosed lesions.

MODIFYING EFFECT OF DIET ON UPPER ALIMENTARY TRACT CANCER IN PERSONS WHO CHEW AND SMOKE TOBACCO

P.N. Notani, Cancer Research Inst., Epidemiology Div., *Dr. Ernest Borges Marg, c/o Tata Memorial Ctr., Bombay 400012, Maharashtra, India* (D-IARC-79-270)

Tobacco chewing and smoking habits carry a high risk for oral cancers, yet not all those who chew or smoke heavily get the disease. This indicates a role for other factors which may have a modifying effect on these risks. Preliminary analysis of existing records indicated a reduction in oral cancer risk in persons with tobacco chewing and smoking habits whose diet included eggs, meat or fish (Ind. J. Cancer, 13, 1976). It is intended to devise methods for collection of dietary information, confirm preliminary observations on oral cancer by a case-control study and extend the study to cover pharyngeal and esophageal cancers.

CANCER REGISTRY IN EASTERN INDIA

R. Chowdhury, Chittaranjan National Cancer Research Centre, Dept. of Epidemiology, *37 S.P. Mukherjee Rd., Calcutta, 700026, West Bengal, India* (D-IARC-78-260)

There is no comprehensive cancer registry in Eastern India (West Bengal, Bihar, Assam and Orissa). Cancer patients from these states belonging to various groups with different socio-economic characteristics are referred to cancer hospitals and other hospitals of Calcutta for treatment. A cancer registry has been set up at the Epidemiology Dept. of Chittaranjan National Cancer Research Center, Calcutta, to provide data for studying aetiology, epidemiology, treatment and end results of malignant diseases. The basic objectives of this registry include: (1) study of frequency distribution of different types of cancer in this area; (2) definition of high risk profiles; and (3) determination of trends and aetiological factors.

EPIDEMIOLOGICAL STUDY OF CARCINOMA OF THE UTERINE CERVIX RELATED TO BATHING HABITS

M.S. Dvivedi, Cancer Hospital, *Indore 452001, Madhya Pradesh, India* (D-IARC-79-274)

It is an established fact that carcinoma of the uterine cervix is more prevalent in low socioeconomic groups even in developed areas. There is a possibility that low socioeconomic groups do not have proper washing facilities in their dwelling places. It is presumed that women who submerge the pelvis in a bath tub might cleanse the vaginal passages more effectively than those who take a shower. In India it is rare to have a bath tub in the bathroom even in the urban population. The usual method of taking a bath is by a bucket and mug. In the rural areas the source of water is either tanks, rivers or rivulets and either the women bathe at their own house using a bucket and a mug or at these other sources of water. In the present study we are studying habits of patients reporting with carcinoma of the uterine cervix for treatment at this center. We are also studying the bathing habits of the husbands of the patients with particular reference to circumcision, retraction of the prepuce during washing and cleaning smegma. This study has been undertaken with a view to studying the status of genital hygiene of patients with carcinoma of the uterine cervix. The non-circumcised husbands are questioned to determine how often they remove the smegma when taking a bath. The distributional pattern of the patients according to these habits may give some indication of causative factors of this disease.

NATURAL BACKGROUND RADIATION AND CANCER FREQUENCY IN HUMAN POPULATION GROUPS

S.P. Allwright, University of Dublin Trinity College, St. James Hospital, Dept. of Community Health, *James St., Dublin 8, Ireland*

Studies investigating the relationship between natural radiation and cancer have produced varying and inconclusive results. The objective of this study is to determine type specific age standardized cancer death rates in Ireland in relation to defined areas of high and low background radiation. Regions of probable high and low radiation have been selected on the basis of existing geological data. Radiation levels, both indoor and outdoor, in these areas will be monitored. The unit area for radiation monitoring will be ten sq km, based on the National Reference Grid. Cancer mortality in the regions where radiation has been measured will be determined, also based on the ten sq km unit of area.

CASE-CONTROL STUDY OF CANCER OF THE URINARY TRACT IN THE PROVINCE OF TURIN, ITALY

B. Terracini, Universita degli Studi di Torino, Istituto di Anatomia e Istologia Patologica, *Via Santena 7, I10126 Turin, Italy* (D-IARC-79-336)

The age-adjusted incidence rate of bladder cancer (including papillomas) in men living in the city of Turin around 1970 was 21.2 per 100.00 person-years while the corresponding rate for the rest of the Province is 10.8. The absolute number of cases per year is on the order of 120 in the city and 70 in the rest of the Province. A case-control study has been undertaken in order to collect information on smoking experience, alcohol and coffee drinking habits, previous use of artificial sweetners, social class and occupational history throughout life. The latter refers to both occupation titles and the industry in which employed. Social class is estimated based on present or last occupation as well as number of years at school and ratio between number of people living in the family unit and number of rooms. Only residents in the Province are interviewed. The survey is being conducted in three of the eight urological hospital departments of the Province of Turin and only hospital based controls are used. It is planned to extend the study to all urological hospital departments operating in the Province and to add population-based controls for residents in the city of Turin. Preliminary results on 75 cases-hospital control pairs have been submitted for publication.

EPIDEMIOLOGICAL DATA COLLECTION ON STOMACH CANCER AND ITS PRECURSORS

M. Crespi, Istituto Regina Elena per lo Studio e la Cura dei Tumori, Cancer Detection Center, *viale Regina Elena 295, 00161 Rome, Italy* (D-IARC-79-329)

Stomach cancer cases will be collected prospectively in the centers involved in the project for the next three years. A detailed inquiry on dietary habits, socio-economic status and occupational environment will be performed on each case and in individuals with predisposing conditions and in a control group, both matched for sex and age. The centers involved represent areas with different mortality rates for stomach cancer. New diagnostic techniques for the detection of cancer in early stages and for known predisposing conditions will be tested during this study and a new approach for a network aimed at the collection of high risk individuals, based on cooperation between doctors involved in primary medical care and the reference centers, will be implemented.

MORTALITY, INCIDENCE AND PREVALENCE AS INDICATORS OF THE MAGNITUDE OF THE CANCER PROBLEM WITHIN AN ITALIAN REGION

V. Mastrandrea, Universita degli Studi di Camerino, Inst. of Hygiene, *62032 Camerino, Italy* (D-IARC-79-318)

Within the Marche region, located in Central Italy, as within most of the country, there is heterogeneity as far as demographic, socio-economic and environmental characteristics are concerned. Taking into account these considerations, the geography of Marche and the findings of a previous study, an investigation will be carried out for the period 1971 to 1981 into the distribution of mortality, incidence and prevalence by individual tumor sites in the coastal, hill and mountain zones of this region which can be respectively considered urban, semi-urban and rural. The three zones may represent an ideal compromise between the need for units small enough to be homogenous for demographic and environmental characteristics that might influence cancer risk and yet large enough to provide stable estimates. Mortality, incidence and prevalence data are abstracted from death certificates from the 246 municipalities of the Marche region and from the clinical record cards available in the 90 hospitals of the same region.

2.1625,

CARCINOGENICITY OF ASBESTOS DUST

A.F. Donna, General City Hospital of Alessandria, Anatomic & Histologic Pathology Inst, *Via Venezia 18, Alessandria, Italy* (D-IARC-79-315)

Pleural mesothelioma would appear to have a low overall incidence in Italy. In some regions of the country such as Piedmont, Liguria and Friuli, the incidence is significantly increased, being highest in the district of Alessandria in Piedmont. The aim of the study is to confirm the reported high incidence in Alessandria and to clarify the role of asbestos dust through questioning of individuals about work and environmental conditions, as well as through biopsy or necropsy confirmation of diagnosis.

CANCER MORTALITY AMONG ATOMIC BOMB SURVIVORS IN HIROSHIMA PREFECTURE

M. Kurihara, Hiroshima University, Research Inst. of Nuclear Medicine & Biology, Dept. of Epidemiology & Social Medicine, *2-3 Kasumi 2 Chome, Hiroshima 734, Hiroshima, Japan*

The atomic bomb survivors in Hiroshima Prefecture were estimated in 1975 to be nearly 180,000. Using the data bank containing information about the survivors in our institute, a survey on cancer mortality among the survivors from 1965 onwards is being conducted. This includes comparison with mortality in the general population of all Japan and in the non-exposed population of Hiroshima Prefecture. The mortality statistics for 1968, 1969 and 1970 will be obtained in 1979.

PATHOEPIDEMIOLOGICAL STUDY OF MALIGNANT LYMPHOMA IN KAGOSHIMA PREFECTURE OF JAPAN

E. Sato, Kagoshima University, Faculty of Medicine, Dept. of Pathology, *1208-1 Usuki-Cho, Kagoshima City 890, Kagoshima, Japan* (D-IARC-79-347)

Several recent studies have shown that a considerable number of patients with T-cell leukaemia in Japan are born in Kyushu district, particularly in Kagoshima prefecture. The aim of this study is to explore the histopathological, immunological and epidemiological characteristics of malignant lymphoma in this prefecture. The annual age-adjusted incidence rate based on the 849 biopsy specimens in the file of our institute in the past twelve years is 4.0/100,000 persons for male and 2.1 for female. Histo-

logical review, electron microscopical observation, assessment of lymphocyte subpopulations, HL-A typing and serological analysis are being carried out and correlated with the age, sex and geographical distribution of malignant lymphoma.

MORTALITY STUDY OF STEEL WORKERS

K. Nakamura, National Inst. of Industrial Health, Dept. of Industrial Epidemiology, *2051 Kizuki Sumiyosityo, Kawasaki, Kanagawa, Japan* (D-IARC-79-352)
Excesses of respiratory cancer among coke oven workers are considered to be related to the exposure to coal tar effluents. To study whether there are any other carcinogenic risk factors in the environment of iron and steel producing plants, about 300,000 steel workers who had worked for at least 1 year at the beginning of 1973 in one of 127 plants in Japan were registered as members of the study cohort. Ascertainment of deaths will be obtained from the family registry system in Japan and death certificate information will be collected from the District Legal Affairs Bureau. In a preliminary stage, the cohort will be followed up retrospectively to the end of 1976, but follow-up thereafter will be continued.

STUDY OF NUTRITION, STEROID METABOLISM AND THE INCIDENCE OF FEMALE CANCER

M. Kodama, Aichi Cancer Center Research Inst., Dept. of Chemotherapy, *81 1159 Kanokoden Tashiro-cho, Chikusa-ku, Nagoya 464, Aichi, Japan* (D-IARC-79-363)
In various ethnic groups the risk for breast cancer is often inversely related to that for cervical cancer. The hormonal environment of the host may somehow be implicated in the induction of these cancers. The relation between the nutritional level, steroid metabolism and the incidence of cervical and breast cancers will be investigated among the inhabitants of urban and rural districts of Japan. The characteristics of patients with such neoplasms will be compared with those of populations with differing cancer risks. The steroid metabolism of each subject will be assessed by estimating the excretions of 14 neutral steroids with 24 hr. urine. Initial results have been published in the Journal of the National Cancer Institute (54:1023-1029, 1975; 54:1275-1282, 1975; 54:41-47, 1977 and 59:49-54, 1977, and 61:35-39, 1978).

EPIDEMIOLOGICAL STUDY OF BLADDER CANCER

Y. Ohno, Nagoya University, School of Medicine, Dept. of Preventive Medicine, *65 Tsurumai-cho, Showa-ku, Nagoya 466, Aichi ken, Japan* (D-IARC-79-368)
In Japan, the age-adjusted mortality rate for bladder cancer has levelled off in males and there is a possible downward trend for females over the last two decades. These trends were observed despite the recent remarkable increases in potentially hazardous environmental agents. In addition, the proportion of bladder cancer and kidney cancer deaths has been constant, 7:3, over these 20 years. These findings are very suggestive of the aetiological importance of host factors in bladder cancer production. Host factors and several environmental factors are now being investigated accordingly in Metropolitan Nagoya by a case-control study. Along with this investigation, familial cases are compared with non-familial cases in respect to tryptophan metabolism, HL-A types and others. Geographic clusters of bladder cancer deaths by city and county have been tested by a newly developed significance test, based on a Monte Carlo method. The test revealed no significant clusters of either high or low bladder cancer mortality in Japan from 1969-1971.

MALIGNANT NEOPLASMS OF THE GALLBLADDER AND BILE DUCTS IN JAPAN

S. Tominaga, Aichi Cancer Center Research Inst., Epidemiology Division, *81 1159 Kanokoden Tashiro-cho, Chikusa-ku, Nagoya 464, Aichi, Japan* (D-IARC-79-372)
This study aims to describe geographical distribution and time trends of malignant neoplasms of the gallbladder and bile ducts in Japan and to discover aetiological factors by relating various environmental factors and other related diseases to mortality from biliary tract cancer. Analysis comparing mortality rates from malignant neoplasms of the gallbladder and bile ducts and food intake by prefecture suggest that dried noodles, pork and fish might be associated with this cancer. Relationships between biliary tract cancer and gallstones and other biliary tract diseases are now under investigation.

TRENDS OF CANCER INCIDENCE AND SURVIVAL OF CANCER PATIENTS IN OSAKA

A. Hanai, Center for Adult Diseases, Dept. of Field Research, *3-3 Nakamichi 1-Chome, Higashinari-ku, Osaka 537, Japan, Japan*
Age-adjusted incidence rates in Osaka have been calculated for each three-year period since the Osaka Cancer Registry started. During these 15 years substantial changes have been observed in the time trends of cancer incidence. The five-year survival rates of cancer cases in the general population were ascertained in Osaka for the first time in Japan. Five-year relative survival rates for cases diagnosed as cancer during 1971-72 were calculated using the registry data linked with the file of all death certificates of Osaka residents during 1971-77. Survival rates varied in different localities within Osaka prefecture. These studies are continuing.

STATISTICAL ANALYSIS OF MALIGNANT AND NON-MALIGNANT DISEASES AND ASSOCIATED LESIONS IN 300,000 AUTOPSIES IN JAPAN IN 1958-1974

T. Miyaji, Japanese Inst. of Pathology, *Sozecho 12, Iida Bldg., Osaka 530, Osaka, Japan* (D-IARC-79-379)
Since the registration of autopsies in Japan started in 1958, over 95 percent of autopsies have been listed every year in the Annual of Pathological Autopsy Cases. The data in the republications are being prepared for entry into a computer for statistical analysis. As the autopsy rate in Japan has been about 3 percent, these cases do not reflect accurately the distribution of causes of death in Japan. However, the analysis of 300,000 autopsies will shed some light on the epidemiology of malignant and non-malignant diseases in the country.

EPIDEMIOLOGICAL STUDY OF THE NATURAL HISTORY OF STOMACH CANCER

A. Oshima, Center for Adult Diseases, Dept. of Field Research, *3-3 Nakamichi 1-Chome, Higashinari-ku, Osaka 537, Japan, Japan* (D-IARC-79-381)
A prospective study is being conducted to estimate the frequency of the development of cancer in persons found to have gastric ulcer, gastric polyp and chronic gastritis. From a follow-up study of the 1,782 patients diagnosed through a screening program as having gastric ulcer, it was shown that there were 30 cancer cases during the follow-up period (average 5.1 years) in contrast with the expected number of 15.5. About half of the 30 cancer cases, however, were diagnosed as cancer within a year of the diagnosis of gastric ulcer and should have been considered as false negative cases. These data suggest that those patients with a diagnosis of gastric ulcer should be regarded as a high risk group, although a hypothesis of the malignant change of gastric ulcer is not supported. A follow-up study of about 10,000 patients on whom endoscopic biopsy tests were conducted at this Center and whose diagnoses were histologically confirmed is now being prepared.

PROSPECTVE STUDY OF NASOPHARYNGEAL MALIGNANCIES (CARCINOMA AND MALIGNANT LYMPHOMA)

S. Sawaki, Yokohama City University, School of Medicine, Dept. of Otolaryngology, *3-46 Urafune, Minami-Ku, Yokohama 232, Kanagawa Ken, Japan* (D-IARC-78-366)

The incidence of nasopharyngeal carcinoma is generally low in Japan. However, malignant nasopharyngeal lymphoma is more frequently observed than in other countries, the ratio of these malignancies being four carcinomas to one lymphoma. It is proposed to collect the clinical records of these two malignancies throughout Japan, and to assess the descriptive epidemiology as the provincial incidence seems to vary. The anti-viral capsid antigen antibody titre will be measured in both histological types to determine their relation to the Epstein-Barr virus.

ETIOLOGICAL FACTORS OF HEPATOCELLULAR CARCINOMA IN CHINESE AND ABORIGINES OF WEST MALAYSIA

E. Sumithran, Universitti Malaya, Medical Faculty, Dept. of Pathology, *Pantai Valley, Kuala Lumpur, Malaysia* 2211 (D-IARC-79-406)

Liver cancer is one of the most common malignancies in Malaysia occurring frequently among the Chinese and Orang Asli (aborigines). Necropsy and liver biopsy specimens showing hepatocellular carcinoma are examined by orcein, immunoperoxidase and immunofluorescence for the presence of HBA. Patients with liver cancer are examined for HBs Ag. Each Orang Asli patient admitted to the Gombak Orang Asli Hospital is accompanied by other members of his family. The blood of these persons, who constitute a control group, is examined. Chronic liver disease associated with the hepatitis B antigen seems to be an important factor in the etiology of liver cancer in the Orang Asli. It is proposed to examine the food eaten by the Orang Asli for aflatoxin.

MORTALITY FROM CANCER IN POLAND, 1960-1974

J. Kopczynski, Akademia Medyczna w Warszawie, Inst. of Social Medicine, Dept. of Epidemiology, *Oczki 3, 02007 Warsaw, Poland* (D-IARC-78-411)

Age- and sex-specific mortality rates for the most common cancer in Poland have been computed on a yearly basis for the period 1960-1974 in order to assess trends. No definite tendency for all sites of cancer could be detected among women in 1965-1974 when age was allowed for. There was a sharp increase in mortality from malignant neoplasms of the lower respiratory tract, particularly in males; gastric cancer mortality fell consistently in both sexes during the study period, whereas death rates for breast cancer increased markedly; mortality from cancer of the uterus declined moderately during the period; there was an increase in mortality from cancer of the large bowel as well as rectal cancer; mortality from leukaemia rose among people of both sexes over 55 years of age.

INCIDENCE OF DIFFERENT HISTOLOGICAL TYPES OF STOMACH CANCER IN WARSAW

Z.L. Wronkowski, Instytut Onkologii im Marii Sklodowskiej Curie, Dept. of Cancer Control & Epidemiology, *15 Wawelska St., 00973 Warsaw, Poland* (D-IARC-79-461)

There are conspicuous differences in the incidence of stomach carcinoma in different populations. Stomach cancer still remains a leading malignancy in Poland and the high incidence rates could be caused by changes in diet during the second world war and the post-war period. The main objectives of the present study are to investigate the distribution of two types of stomach carcinoma, i.e. 'intestinal' and 'diffuse', in the population of the city of Warsaw and to analyse the time trends for three decades. The study design is retrospective. All available pathological slides for stomach cancer patients from the city of Warsaw will be collected and reviewed. Age-adjusted rates will be computed.

CANCER INCIDENCE AMONGST PETROCHEMICAL WORKERS IN WARSAW REGION

Z.L. Wronkowski, Instytut Onkologii im Marii Sklodowskiej Curie, Dept. of Cancer Control & Epidemiology, *15 Wawelska St., 00973 Warsaw, Poland* (D-IARC-79-460)

The purpose of this study is to determine whether incidence of cancer among petrochemical workers differs from the rates in two control groups, i.e., farmers and the general population in the Warsaw region. The population under study consists of all workers of the Petroleum Plant in Plock who started work after January 1, 1965 - approximately 15,000 individuals. A control group of farmers, individually matched by year of birth and sex, will be used. Both groups will be followed up and cancer cases will be ascertained through linkage of records of the study and control groups and those of the Warsaw Tumor

Registry. Data on risk factors for study and control groups will be collected. Age, by individual year, sex and site specific cancer incidence rates will be compared with the expected numbers based on incidence rates in the Warsaw region. Man years of exposure will be calculated for specific cohorts by age and sex so that a dose-response relationship may be tested.

PROSPECTIVE STUDY OF PATIENTS INJECTED WITH THOROTRAST (PORTUGUESE LONG-TERM SIDE EFFECTS OF THOROTRAST STUDY GROUPS)

J.S. Horta, Universidade de Lisboa, School of Medicine, *Cidade Universitaria, Lisbon 4, Portugal* (D-IARC-98-462)

Since the late 1950's neoplastic and other lesions, found mostly in the liver and bone marrow, have been reported in Portuguese patients who were injected some years earlier with thorotrast (a colloidal suspension of thorium dioxide, used mostly as an intravascular radiological contrast medium). A prospective survey of about 2,000 individuals injected with this agent between 1930 and 1950, together with pathological, clinical and laboratory studies, was started in 1961 by the Portuguese Side Effects of Thorotrast Study Group. A significantly higher risk of death from malignancies (mostly liver tumors and acute leukaemia) has been shown among thorotrast recipients compared with controls. This study is continuing. It is hoped that follow-up of these Portuguese patients will continue until the near extinction of surviving patients (now numbering about 200) so that more data relevant to the possible harmful effects to man of other alpha-emitters, such as plutonium, may be collected. The risk of lung and bone cancer is of particular interest with a suggestive increase in bone sarcoma already reported in the literature.

EPIDEMIOLOGICAL FACTORS IN GASTRIC CANCER, CLUJ DISTRICT, ROMANIA

G. Bolba, Oncological Inst. of Cluj-Napoca, Dept. of Epidemiology & Statistics, *Republicii Nr. 34-36, R3400 Cluj-Napoca, Romania* (D-IARC-79-471)

Study of cancer incidence in Cluj district (1974-1975) shows that among males gastric cancer is most prevalent (42.2 per 100,000 per annum) being most widespread in the rural areas (about 73.0). Among females, breast cancer was most prevalent (27.0) followed by cervix uteri (23.8) and stomach (22.1). Previously, the rank order was: 1-cervix uteri, 2-stomach, 3-breast cancer. The correlation between nitrosamines and gastric cancer is being studied, estimating the secondary amines in the traditional foodstuffs and the nitrate and nitrite in drinking water in rural areas.

COHORT STUDY ON HEPATITIS B CARRIERS AND LIVER CANCER

W.O. Phoon, University of Singapore, School of Medicine, Dept. of Social Medicine & Public Health, *Sepoy Lines, Singapore 3, Singapore* (D-IARC-79-477)

Liver cancer is one of the most common forms of cancer in Singapore, especially among Chinese males. Seroepidemiological studies have shown that the frequency of exposure to hepatitis B virus (HBV) and the frequency of chronic carriers is much higher among liver cancer patients than among controls. The main objectives of the present study are to identify the carriers and non-carriers of HBV and to measure their risk for developing liver cancer. A group of at least 5,000 Chinese males over 45 years of age will be bled and their sera will be tested for various markers of HBV. Re-bleeding of those patients found to be positive for various markers of HBV will be attempted to confirm their carrier status. The liver cancer cases which develop in this cohort will then be identified by record linkage with the National Cancer Registry in Singapore. In addition, an attempt will be made to study the other epidemiological factors which may have a bearing on the onset of liver cancer. The study design is prospective by nature.

ENVIRONMENTAL AND DEMOGRAPHIC STUDIES ON ESOPHAGUS CANCER IN TRANSKEI

S.J. Van Rensburg, South African Medical Research Council, National Research Inst. for Nutritional Diseases, Division of Nutritional Pathology, *P.O. Box 70, Tygerberg 7505, Cape Province, South Africa* (D-IARC-79-489)

Esophageal cancer shows a marked geographical variation in incidence in the Transkei. Three main lines of investigation are being undertaken: 1) Agricultural associations: the following studies are being conducted on a broad scale in high and low incidence districts; soil profiles and pedalogical classification, soil mineral and trace elements, elements in plants and water and the distribution of mycotoxin in edible produce. 2) Environmental carcinogens: analyses of nitrosamines in prepared food and beer from high and low incidence areas, mycotoxin analyses of prepared and stored food from high and low incidence areas, biological screening program of dietary staples, snuff, beer and home-grown tobacco smoke condensate on rats. 3) Population studies: case-control questionnaire study, a clustering study -geographic, temporal and familial - and detailed ecological studies in cluster and adjacent areas free of esophageal cancer, if any.

2.1661,

PRIMARY LIVER CANCER RATE AND AFLATOXIN INTAKE IN TRANSKEI

S.J. Van Rensburg, South African Medical Research Council, National Research Inst. for Nutritional Diseases, Division of Nutritional Pathology, *P.O. Box 70, Tygerberg 7505, Cape Province, South Africa* (D-IARC-79-490)

The objective is to establish if the international data on the relationship between liver cancer and aflatoxin intake are also applicable to the Transkei. Prepared food samples are being collected from four districts in Transkei for the chemical analysis of aflatoxins. Cancer incidence will be assessed by simple hospital registration, and, further, by the incidence rates in mineworkers originating from the study area.

RELATION BETWEEN CANCER INCIDENCE AND ENVIRONMENTAL FACTORS

C.R. Rylander, Goteborgs Universitet, Dept. of Environmental Hygiene, *411 Vasaparken, S40010 Goteborg, Sweden* (D-IARC-79-502)

The geographical distribution of various types of neoplasms is studied in Sweden. Preliminary data on liver cancers among males demonstrate that the 3 big cities in Sweden have an increased rate in comparison to the remainder of the country. This difference is less pronounced among females. Further analyses are performed to investigate exposure in chemical industry and exposure through alcohol consumption.

MEDICAL CARE UTILIZATION IN STOCKHOLM - REQUIREMENTS AND REALITY

E. Allander, Inst. of Social Medicine, *S14186 Huddinge, Sweden* (D-IARC-78-448)

The first aim of this study is to develop methods for record linkage between data bases for epidemiological studies. The data bases of special interest are the Swedish Register of Death Certificates and the Stockholm Register of In-patient Care. The second aim is to use these data to study the epidemiology of acute myocardial infarction and fractures on the hip (cancer may be included in the future).

REGIONAL TUMOR REGISTRY FOR SOUTHERN SWEDEN

T.R. Moeller, University Hospital of Lund, Dept. of Oncology, *E. Blocket, S22185 Lund, Sweden* (D-IARC-79-512)

In the new organization proposed for oncological care in Sweden, it is planned to found seven oncological centers, in each of which a regional tumor registry will be established. These registries not only collect the reports on new cancers in the region but also take part in clinical trials, epidemiological studies and similar activities undertaken in the region. Work is now in progress to establish a regional tumor registry with these functions in the southern part of Sweden.

RETROSPECTIVE EPIDEMIOLOGICAL STUDY OF HEALTH HAZARDS IN THE RUBBER INDUSTRY

B.E. Holmberg, National Board of Occupational Safety & Health, Occupational Toxicology Section, *P.O. Box 10026, S10026 Stockholm, Sweden* (D-IARC-79-519)

All workers in two large rubber companies employed between January 1, 1930, and December 31, 1972, who worked for more than one year, will constitute the cohort. The cohort will be subdivided according to department: mixing department and other production departments. White collar workers form a control group. These lists of workers will be completed by the personal identification number and compared with the official death registry and the cancer registry.

SOFT-TISSUE SARCOMAS AND EXPOSURE TO PHENOXY ACIDS - AN EPIDEMIOLOGICAL STUDY

L.Q. Hardell, Regionsjukhuset, Dept. of Oncology, *90185 Umea, Sweden* (D-IARC-79-522)

During 1970-1976, 56 men and 36 women with malignant soft-tissue sarcomas were admitted to the Dept. of Oncology at the Regional Hospital in Umea, Sweden. Forty-four of these men were workers and

7 stated that they had previous relatively heavy exposure to phenoxyacetic acids. These findings have been published in Laekartidningen 74: 2753-2754, 1977. The aim of the present study is a more thorough investigation, performed as a case-control study, of a possible connection between exposure to phenoxyacetic acids, 2,4-D and 2,4,5-T, and malignant soft-tissue sarcomas. The control group will be matched by geographical region, sex and age.

OCCUPATIONAL DISTRIBUTION AMONG LUNG CANCER PATIENTS COMPARED TO THOSE WITH CHRONIC BRONCHITIS, BRONCHIAL ASTHMA AND SARCOIDOSIS IN BERNE

M. Scherrer, University of Bern, Outpatient Clinic, Dept. of Internal Medicine, *Freiburgstrasse, CH3010 Bern 3012, Switzerland* (D-IARC-79-531)

It is believed that with a highly developed modern industry various carcinogenic substances are produced (synthetic materials, metals etc.). Inhalation of noxious materials at work may, therefore, be a further cause of the development of lung cancer, in addition to smoking. The distribution of different occupational groups among patients with lung cancer and selected pulmonary conditions is being studied in order to find out whether workers in the chemical, synthetic or metal industry are more frequently affected than other occupational groups.

MORTALITY STATISTICS

H.E. Hansluwka, World Health Org., Division of Health Statistics, *1221 Ave. Appia, Geneva 27, Switzerland* (D-IARC-79-532)

Statistical data concerning mortality following the List 'A' of the International Classification of Diseases are collected on a world-wide basis, processed, stored and published annually (Volume 1 of the World Health Statistics Annual). Data on cancer mortality according to the three-digit list of ICD are collected and stored in WHO's data bank. Epidemiological and statistical analyses of cancer mortality are periodically published as a special subject in the World Health Statistics Report (WHSTR) e.g. Breast, WHSTR, No 6, 1975; Uterus, WHSTR, No 8, 1975; Digestive Organs and Peritoneum, WHSTR, No 3, 1976; Hodgkin's Disease, WHSTR, No 2, 1977; Lung, WHSTR, No 2, 1977. A project for the development of a comprehensive cancer information subsystem is underway.

RETROSPECTIVE STUDY OF CANCER MORTALITY RELATED TO PLACE OF RESIDENCE

C. Schlatter, Eidgenossische Technische Hochule Zurich, Inst. for Toxicology, *Schorenstrasse 16, 8603 Schwerzenbach, Switzerland* (D-IARC-79-539)

It was shown by Blumer (Schweiz. Med. Wschr. 106, 503 (1976)) that cancer mortality was strongly dependent on place of residence. People living in the immediate vicinity of the central road of a city in Switzerland died about 9 times as frequently from cancer as people in remote areas of the same city. In a recalculation of the raw data (Schweiz. Med. Wschr. 107, 312 (1977)) the results were confirmed in that the cancer mortality of the group living near the road was higher by a factor of two than expected on the basis of age-adjusted cancer mortality in Switzerland. It is planned to determine if a similar relationship can be found in other places in Switzerland.

CHRONOLOGICAL OBSERVATION OF EPIDEMIOLOGICAL CHARACTERISTICS OF LUNG CANCER IN TAIWAN

S.P. Yang, National Taiwan University, College of Medicine, Dept. of Internal Medicine, *1 Jenai Rd. Section 1, Taipei, Republic of China* (D-IARC-79-540)

A previous study indicates that lung cancer in Taiwan has the following epidemiological characteristics: 1. An increasing rate which is the highest among malignant neoplasms in the past 20 years. 2. A male to female ratio of 2 to 1, which has been the same for the past 30 years. 3. A high frequency of adenocarcinoma even in males (34.3% for males and 58.7% for females). 4. A recent rapid increase which cannot be explained solely by cigarette smoking. In order to determine whether these epidemiological characteristics will change in the future, a time trends study is underway for each five-year interval, analyzing available vital statistics data and clinical material collected from major hospitals islandwide (there is still no islandwide cancer registration system) and comparing the results of the 2nd lung cancer prevalence survey (in conjunction with the 5th tuberculosis prevalence survey) in 1977-1978 with those of the first survey carried out 5 years ago.

MORTALITY FROM CANCER OF THE COLON AND RECTUM IN RELATION TO FOOD SALES

A. Delachaux, Universite de Lausanne, Institut de Medicine Sociale et Preventive, *Bugnon, Case Postale 611, 1011 Lausanne, Switzerland* (D-IARC-79-536)

Standardized mortality ratios for cancers of the colon and rectum show significant differences among the 25 cantons of Switzerland. Data on sales of foodstuffs have been obtained from one of the two major cooperatives. The deaths for the 7 years 1969-1975 and the corresponding populations have been calculated for the same areas as for food sales. The latter will be converted into nutritional content (fibre etc.) and compared with the death rates. A search will be made for similar data in other countries.

BURKITT'S LYMPHOMA PROJECT, MARA REGION, TANZANIA

G.R. Brubaker, Shirati Mission Hospital, *Musoma, Tanzania* (D-IARC-79-543)

The general objective is to study the epidemiology of Burkitt's lymphoma (BL) and, more specifically, to investigate the role of hyper-endemic malaria in BL causation. In order to determine whether hyperendemic malaria is necessary for BL development, a malaria suppression trial is being carried out. Chloroquin tablets are distributed twice monthly to approximately 90,000 children aged 0-10 years in order to reduce malaria to hypoendemic levels. The malaria suppression was initiated in 1977 and will be continued for five years, during which time the incidence of BL will be carefully monitored in the area.

EPIDEMIOLOGY OF CANCER OF CERVIX UTERI IN THAILAND

S. Boonyanit, Mahidol University, Siriraj Hospital & Medical School, Dept. of Obstetrics & Gynecology, *2 Prannog Rd., Bangkok 7, Thailand* (D-IARC-78-480)

Cancer of cervix uteri is one of the most common neoplasms in Thailand and is one of the principal causes of death. During the past years cancer of the cervix comprised about 17 percent of all cancer among females. The main objectives of the study of case characteristics are to (1) investigate the relation of age, parity, sexual habits, use of IUD and contraceptive pill, socioeconomic status, menstrual and marital history, race, religion, diet, education, pre-existing pathology and family history of cancer to cancer of cervix; (2) elucidate the relation of personal hygiene, parasitic fungus and viral infection to this disease; (3) determine the reasons for the high proportion of adenocarcinoma of cervix which over the past 15 years has risen from 3 percent to nearly 19 percent, and for the apparent fall in average age of patient over the past ten years.

ENDEMIC PLEURO-PERITONEAL DISEASE IN RURAL TURKEY

Y.I. Baris, Hacettepe Universitesi, Faculty of Medicine, Dept. of Chest Diseases, *Ankara, Turkey* (D-IARC-79-550)

The Institute of Mineral Research and Exploration of Turkey has shown that certain regions in Turkey are rich in asbestos. Preliminary studies have shown that there are many villages in Turkey where pleural calcifications (Hacihasan village), both pleural calcifications and pleural and peritoneal mesotheliomas and other malignancies (Tuzkoey) and pleural mesothlioma (Karain village) are common. These villages are located in Central Anatolia; the diseases are familial but not hereditary. Geological studies have shown that there are no deposits of commercial asbestos in the vicinity of these villages, nor any asbestos mines, mills or factories. It is believed that these diseases are non-occupational. Retrospective and prospective epidemiological and clinical studies are being undertaken to solve this problem.

2.1679,

AN EPIDEMIOLOGICAL STUDY OF LEUKAEMIA INDUCED BY EXPOSURE TO DIFFERENT CHEMICALS

M.B. Aksoy, Istanbul Universitesi, School of Medicine, Dept. of Internal Medicine, *Bayezit, Istanbul, Turkey* (D-IARC-79-557)

Despite the fact that there is a significant reduction in the incidence of haematopoietic insults, such as apiastic anaemia and leukaemia, after the strict prohibition of the use of benzene as a solvent in Turkey, other chemicals (those used in the textile industry and asbestos) may still be involved in the occurence of leukaemia among the working population. The scope of the present project is to perform an epidemiological study as well as clinical and laboratory investigations directed towards the detection of the incidence and the types of leukaemia produced in those chronically exposed to these chemicals. It is also believed that the detection of the patients involved, while they are still at the pre-leukaemic stage, may be of importance. The cytochemical and immunological alterations likely to be observed in such subjects constitute another interesting aspect of the task. Chromatographical analysis of the chemicals in question will be undertaken.

PROSPECTIVE STUDY OF BURKITT'S LYMPHOMA, WEST NILE DISTRICT, UGANDA

G. Olwitt, East African Virus Research Inst., *P.O. Box 369, Arua, Uganda* (D-IARC-79-559)

The main objective is to study the aetiological involvement of the Epstein-Barr virus (EBV) in Burkitt's lymphoma (BL). Additional objectives are to study the epidemiology of the EBV and BL in the West Nile district, and the role of hyperendemic malaria in BL causation. cohort of 42,000 children aged 0-8 years was bled in an initial phase from 1972-1974. During the subsequent case detection, fourteen BL cases were diagnosed in the children who were bled. The testing of the 'pre-sera' and appropriate controls showed that viral capsid antigen antibodies to the EBV had already been elevated in the BL candidates up to four years before tumour manifestation (Nature 274, (5673) 756-761, 1978). Other EBV antibody activities (early antigen and Epstein-Barr nuclear antigen) were not elevated in the pre-BL sera and the case detection in the study cohort will continue until 1979 in order to study the mechanism of how EBV infection promotes BL development. The study of BL epidemiology has confirmed that the tumour still shows significant time-space clustering and seasonal variation, thus favouring an infectious aetiology. The epidemiology of the EBV is being studied in number of sample groups which were bled repeatedly during the years 1973-1977. The testing for EBV antibodies in the sera is now progressing at the laboratory at IARC, Lyon. The BL case detection in the West Nile district will continue through 1979. Since the testing of the 14 pre-bled BL sera in 1977, 5 new pre-bled BL cases have been detected and will be tested for anti-EBV activities in 1979. The analysis of the malaria data collected in the longitudinal s'.ey in the West Nile has indicated that malaria parasitaemia declined drastically in the West Nile between 1973 and 1977. The malaria slides are now being re-examined to ensure that this observation is true.

2.1681,

STUDY OF A BRITISH SHIPYARD POPULATION WITH REGARD TO BRONCHIAL CARCINOMA INCIDENCE IN MEN WITH PLEURAL PLAQUES

J.R. Edge, University of Newcastle Upon Tyne, Postgraduate Department, *6 Kensington Terr., Newcastle Upon Tyne NE1 7RU, United Kingdom* (D-IARC-79-563)

Pleural plaques, both fibrous and calcified, have been widely described in the neighbourhood of asbestos mines and in populations using asbestos industrially. They are commonly thought to be benign lesions merely indicating prior asbestos exposure. The present study concerns a shipyard population of 7,000 men who have been found to have a high prevalence of pleural plaques (one third of the male population as assessed in 100 consecutive unselected autopsies), and a substantial annual incidence of malignant mesothelioma of the pleura. The clinical impression is that the occurrence of bronchial carcinoma in men showing pleural plaques is substantially increased. A group of Barrow shipyard workers with pleural plaques and a matched group of Carlisle workers from different but non-asbestos-exposed occupations are being compared in a long-term mortality study. The results to date suggest an increased incidence of bronchial carcinoma in the men with pleural plaques of approximately five times that found in the control series. It is intended to continue this study for another five years. Further statistical analysis has revealed a bias because of the inclusion of some clinically diagnosed subjects in the Barrow series, compared with the controls, all of whom had routine radiographs. The increase in the incidence of bronchial carcinoma in the plaque group after this has been allowed for is likely to be nearer twofold that the fivefold initially estimated.

CARDIFF CERVICAL CYTOLOGY STUDY

J.B. Landsman, Medical Research Council, Epidemiology Unit, *4 Richmond Rd., Cardiff CF2 3AS, Wales, United Kingdom* (D-IARC-79-582)

The main objective of the Cardiff Cervical Cytology Study is to evaluate screening for cervical cancer. The study is based on a defined population: all women who have ever been married, aged 25-69, resident within the Cardiff City area. The basic design objective was that all eligible women should be screened three times. The defined population was enumerated by house-to-house visiting, and eligible women were offered appointments for a cervical smear test at specially organized clinics. The study began in late 1965 and the first round of visiting the city finished early in 1971. The defined population numbers some 71,000 women of whom 46,000 (65%) accepted the offer of the test. Subsequent to the first smear women were re-called for second and third smears at two to three yearly intervals. Some 38,000 have so far had second smear and over 30,000 have had a third. The study should provide estimates of the prevalence and incidence of the various pathological states, estimates of false negative and false positive error rates. Death and registration rates for invasive cancer in the Cardiff City area are being monitored.

NATIONAL REGISTRY FOR RADIATION WORKERS

J.A. Reissland, National Radiological Protection Board, Dept. of Physics, *Harwell St., Oxford, England, United Kingdom* (D-IARC-79-584)

The purpose of this study is to investigate by long-term follow-up studies any relationship between occupational exposure to radiation and age-specific causes of death. Any worker who is monitored regularly for exposure to radiation and for whom dose records are kept is entered in the Registry. It is expected to include over 50,000 current workers in addition to those who leave the industry whether by death, retirement or change of job. Once sufficient data on mortality has accumulated, periodic analyses will be carried out with several different control groups chosen from among those workers on the Registry with very low lifetime radiation doses.

CORRELATION OF PATHOLOGICAL TYPES OF OVARIAN NEOPLASMS WITH CHARACTERISTICS OF THE DISEASE

C.R. Gillis, Greater Glasgow Area Health Board, Cancer Intelligence Unit, *520 Bilsland Dr., c/o Ruchill Hospital, Glasgow G20 9NB, Scotland, United Kingdom* (D-IARC-79-529)

All cases of ovarian carcinoma first diagnosed in 1974 and resident in the west of Scotland have been identified. Pathology specimens have been examined by one pathologist. The role of fertility and previous disease in relation to the aetiology of ovarian cancer, and in particular to the individual tumor type, is being investigated by comparison with information collected from appropriate sources. The procedures used to establish diagnosis together with the different types of treatment given have been quantified. The effect of pathological type and staging on survival is being studied.

TRENDS IN SKIN CANCER

V.S. Beral, University of London, London School of Hygiene & Tropical Medicine, Dept. of Epidemiology & Med Statistics, *Keppel St., London WC1E 7HT, England, United Kingdom* (D-IARC-79-606)

The incidence of skin cancer, particularly malignant melanoma, is increasing rapidly in most countries. The present study is concerned with the analysis of routinely available mortality and morbidity data on skin cancers. Its aim is to describe those populations in which the increase in incidence has been most marked. The analysis includes (a) time trends, (b) cohort trends, (c) social class variations, and (d) geographic variations in disease incidence. Particular attention is given to regional variations (urban/rural and international) in skin cancer incidence during the past 20 years and the role of changes in atmospheric ozone in explaining the observed disease pattern. Initial examination of the data suggests that some other explanation is required.

EPIDEMIOLOGICAL STUDIES OF THE RELATIONSHIP BETWEEN RE-USE OF WATER AND HAZARDS TO HEALTH

S.A. Beresford, University of London, Royal Free Hospital School of Medicine, Dept. of Clinical Epidemiology & Social Medicine, *8 Hunter St., London WC1N 1BP, England, United Kingdom* (D-IARC-79-608)

The aim of the studies is to investigate the effects on the health of populations drinking water derived from water sources contaminated with domestic and industrial waste, with particular reference to cancer of the digestive system, and of the genitourinary system. The first stage of the studies is to examine the association between cancer mortality and the source of water supply in terms of the history of pollution and degree of re-use. The hypothesised association arises mainly from the Mississippi River study although other studies have also examined this association. Possible disease outcomes other than cancer will also be investigated to provide a basis for formulating further hypotheses.

GASTRIC CANCER AND NITRATE INGESTION - NITRATE IN DRINKING WATER

P.M. Fraser, University of London, London School of Hygiene & Tropical Medicine, Dept. of Epidemiology & Medical Statistics, *Keppel St., London WC1E 7HT, England, United Kingdom* (D-IARC-79-621)

Evidence is accumulating that populations ingesting large amounts of nitrate have a high mortality from cancer, particularly of the stomach, due to the formation in vivo of carcinogenic nitrosamines. Nitrate levels in some water sources in the eastern regions of England are rising steadily due to extensive use of fertilizer. Mortality from gastric cancer within these regions in 1969-73 is being examined in relation to the nitrate concentration in drinking water 15 to 20 years previously. The objectives of this study are: 1) to establish whether there is an increased risk of gastric cancer in populations exposed to moderately high levels of nitrate in drinking water and 2) to determine a safe level for nitrate in drinking water.

STUDY OF FERTILIZER MANUFACTURERS

P.M. Fraser, University of London, London School of Hygiene & Tropical Medicine, Dept. of Epidemiology & Medical Statistics, *Keppel St., London WC1E 7HT, England, United Kingdom* (D-IARC-79-622)

The hypothesis that high nitrate ingestion causes cancer is being examined in workers exposed to nitrate-containing dust in the manufacture of fertilizer. A census-based study links occupational data from the 1961 and 1971 censuses of England and Wales to mortality data from the National Health Service Central Register.

GLOUCESTERSHIRE STUDY

P.N. Lee, Tobacco Research Council, *Glen House, Stag Pl., London SW1E 5AG, England, United Kingdom* (D-IARC-79-632)

In 1963-1967 information on respiratory symptoms, residential, occupational and medical history, as well as full details of smoking habits, was obtained from 2,377 people in hospitals in Gloucestershire. Those selected formed six groups, namely lung cancer, chronic bronchitis, other chest diseases, cardiac, orthopaedic and other cancer cases. Between 1974 and 1977 an attempt was made to reinterview those still alive and to determine their current smoking habits and respiratory symptoms and to find the cause of death of those who had died. In addition a sample of the living population in Gloucestershire in 1974 was interviewed to determine their smoking habits and respiratory symptoms. The data is now being analysed with four main objectives. Firstly, to determine how the six hospitalized groups differed on factors recorded on the original questionnaire. Secondly, to determine within disorder groups how survival is related to the information recorded originally. Thirdly, to test how representative the survivors are of the living population in Gloucestershire. Fourthly, to investigate changes in symptoms and in smoking habits in the survivors and examine how the progression of the former is related to changes in the latter.

INCIDENCE OF BREAST CANCER IN WOMEN WHO HAVE HAD A TOTAL COLECTOMY AT AN EARLY AGE

E.H. Rang, University of London, St. Georges Hospital Medical School, Dept. of Surgery, *Cranmer Terr. Tooting, London SW17 0RE, England, United Kingdom* (D-IARC-79-642)

There is a high correlation between the intake of dietary fat and the incidence of cancer of the colon and breast. It has been suggested that the amount of dietary fat affects the composition of the gut flora and the concentration of biliery steroids in the gut and that certain bacteria might be able to produce carcinogens in the colon from these steroids. The production by intestinal bacteria of steroidal oestrogens from the biliary steroids has also been demonstrated and suggests a possible role for these bacteria in breast cancer. The purpose of this study is to test the possibility of a relationship between the production or modification of oestrogenic steroids by gut bacteria and the development of breast cancer by seeing whether there is a decreased incidence of breast cancer in women who have had a total colectomy at an early age. It is hoped to follow up about 2,000 women who had a total colectomy and compare the observed number of breast cancers in the group with the number expected if their colons were retained.

CONTROLLED TRIAL OF SMOKING CESSATION

G. Rose, University of London, London School of Hygiene & Tropical Medicine, Dept. of Medical Statistics & Epidemiology, *Keppel St., London WC1E 7HT, England, United Kingdom* (D-IARC-79-643)

The effects of smoking cessation on mortality from cardiorespiratory diseases and cancers will be studied. Some 1,400 male cigarette smokers aged 40-64 were randomly allocated to an intervention group (50% gave up cigarettes for 3 years or more) and a control group. All-causes mortality results are to be reported in December 1978 and cause-specific results in (probably) 1980.

EPIDEMIOLOGICAL ASPECTS OF HODGKIN'S DISEASE IN GREATER MANCHESTER
I. Leck, Christie Hospital & Holt Radium Inst., Epidemiology Unit, *Wilmslow Rd., Withington, Manchester M20 9BX, England, United Kingdom* (D-IARC-79-655)
The hypothesis that Hodgkin's disease is transmissible is being explored in two ways. (1) The importance of a recent report that links such as having attended the same school or work place are no more common between Hodgkin's disease cases than between controls (Smith et al., Lancet 1977, II, 59) is being assessed by seeing whether excesses of such links can be demonstrated between either infectious hepatitis or infectious mononucleosis patients who have been in hospital. (2) Fifteen years cases of Hodgkin's disease in Greater Manchester are being tested for space-time interaction by Knox's method, in order see whether there is any tendency for patients who live close together to develop symptoms either at around the same time or (as might be expected if there was a long incubation period) at intervals of a particular length.

2.1704,
ESTIMATION OF INCIDENCE RATES OF CARCINOMA IN SITU OF THE CERVIX UTERI
D. May, University of Manchester, Dept. of Community Medicine, *Oxford Rd., Manchester M13 9PL, England, United Kingdom* (D-IARC-78-598)
Data has been collected, over a ten-year period and for a number of purposes, relating to cytological screening tests for uterine cervical lesions among women in the North Western (Health Authority) Region of England. Under this project, it is intended to estimate incidence rates and prevalence rates of the condition which gives rise to truly positive cytological test results. The approach is by means of a model and social class, of rates of prevalance, incidence, false-positive errors and false-negative errors. Equations derived from this model are applied to the data in order to determine the underlying rates, with further assistance from information based on the histological follow-up of positive cytological results.

2.1705,
AN EPIDEMIOLOGICAL STUDY OF STOMACH CANCER IN NORTH STAFFORDSHIRE
C.A. Veys, North Staffordshire Medical Inst., Industrial & Community Health Research Centre, *Hartshill, Stoke on Trent ST4 7NY England, United Kingdom* (D-IARC-79-686)
The mortality from stomach cancer in Stoke-on-Trent is one of the highest recorded in the United Kingdom, but the reasons for this are unknown. Some positive associations between stomach cancer and occupation have been observed, in particular with certain dusty trades; and there is also an association with suspended particulate air pollution. For many years in the past, the North Staffordshire area has been noted for its high level of air pollution, which was predominantly caused by smoke emission from local major industries, especially pottery manufacture. Coal mining also predominates and there are many other dusty occupations. The main objective of the study, which is in two parts, is to examine whether occupational factors (especially dust exposure) play a part in the aetiology of stomach cancer in the Stoke-on-Trent area. The investigation will encompass, firstly a detailed examination (in epidemiological terms) of each case of stomach cancer (both male and female) that occurred in the County Borough District of Stoke-on-Trent within the fifteen year period 1961-1975. In addition, prospective case-control study on each person newly presenting with stomach cancer within the succeeding three years (beginning in 1977) will be undertaken. A detailed whole life occupational history will be obtained at interview and matched against that obtained from four controls chosen at random from the population at large. The data will be compared and contrasted for statistically significant differences in the dust exposure between cases and control groups.

LUNG CANCER IN THE ANTIMONY INDUSTRY
J.P. Cunningham, Anzon Ltd., *Cookson Hse. Willington Quay, Tyne & Wear, Wallsend NE28 6UQ, England, United Kingdom* (D-IARC-79-700)
A prospective epidemiological survey of workers engaged in the production of antimony metal, antimony oxide, and antimony sulphide is being undertaken to ascertain whether there is an excess of lung cancer by comparison with local death rates and death rates in other occupations. The survey includes all persons working at the plant on 1/1/1961 or joining after that date, and is likely to continue until 1985 or later. Persons leaving employment are traced. The calculations of expected deaths are age-specific and related to man-years of exposure. The survey covers an adjacent zircon plant, as a control. Other factors studied are smoking, sulphur, arsenic and area of residence.

MEDICAL AND OCCUPATIONAL RECORDS ANALYSIS SYSTEM
K.S. Williamson, Imperial Chemical Industries Ltd., Central Medical Group, *Fulshaw Hall, Cheshire, Wilmslow SK9 1QB, England, United Kingdom* (D-IARC-79-702)
Workers in the chemical manufacturing industry may be exposed to many different chemical compounds in the course of their work. The possible toxic effects of such small but long-term contacts are largely unknown. The object of this study is to bring together data on the mortality and serious morbidity experience of all employees of Imperial Chemical Industries (ICI) in the United Kingdom, with a continuous record of their place of employment and the chemical substances with which they come into contact. This will be an ongoing study, involving follow-up of an average population of about 100,000 over many years. Data will be collected in a machine system and will be capable of analysis in a number of ways, e.g., by cause of death or serious illness in workers exposed to a particular chemical or mixture of chemicals or by tracing the chemical exposure of those contracting a particular disease, etc.

BREAST CANCER AND ORAL CONTRACEPTIVES
D.T. Janerich, State Bureau of Cancer Control, *Empire State Plaza, Tower Bldg. Rm. 565, Albany, New York* 12237 (D-IARC-79-914)
This case-control study was designed to study the possible relationship between oral contraceptives and breast cancer. Our case group consists of women of 45 years of age or younger with breast cancer; controls are matched on the basis of age at first birth. The final case group will consist of 300-400 women. The questionnaire is self-administered and requires full contraceptive and reproductive histories. This study is nearing the end of the data collection stage. The association of prior benign breast disease and oral contraceptive use with breast cancer is currently being analyzed. Family history and oral contraceptive use in relation to breast cancer is also being examined.

2.1709,
BREAST CANCER IN YOUNG WOMEN - THE EFFECT OF PRIOR PREGNANCY
D.T. Janerich, State Bureau of Cancer Control, *Empire State Plaza, Tower Bldg. Rm. 565, Albany, New York* 12237 (D-IARC-78-642)
Women whose first pregnancy occurs at an early age have a lower overall risk of breast cancer than either nulliparous women or those women whose first birth is later in their reproductive lives. In this case-control study, pregnancy histories were studied among 317 parous women who were 45 years old or less when breast cancer was diagnosed. The question of whether or not the protection afforded by early pregnancy occurs immediately or is delayed, similar to early surgical menopause, is being examined.

URANIUM EPIDEMIOLOGY STUDY
R.W. Buechley, University of New Mexico, School of Medicine, Epidemiology Section, *University Hill N.E., Albuquerque, New Mexico* 87131 (D-IARC-79-910)
The health status of uranium miners in the Grants, New Mexico, uranium belt will be studied with special emphasis on those diseases associated with exposure to radon daughters, e.g., lung cancer. A list of about 20,000 persons receiving pre-employment medical examinations has formed the basis of a defined cohort of 4,000 miners who have worked underground for at least one year. The relationships for individual miners of radiation exposure, mining, and smoking will be examined. For the last 15 years exposure levels have been measured. In 1969 new standards reduced allowable exposure by a factor of 5. Ultimately health histories of Grants area miners employed only since 1969 (low radiation levels), Grants area miners employed before 1969 (higher radiation levels), and miners working in Utah and Colorado earlier at much higher radiation levels will be compared and external comparisons made with non-mining populations of the mining area, of other areas of New Mexico, and of the United States as a whole.

MORBIDITY AND MORTALITY AMONG RESERVE MINING COMPANY EMPLOYEES
I.T. Higgins, University of Michigan, Ann Arbor Campus, School of Public Health, Dept. of Epidemiology/Environmental & Industrial Health, *Ann Arbor, Michigan* 48104 (D-IARC-79-877)
This study comprises follow-up of a cohort of men employed at two facilities of the Reserve Mining Company. The attempt is being made to obtain information about all men who have been employed by the Company for one year or more. Mortality from all causes and from specific causes will be compared with expectations based on U.S. and Minnesota rates and within the cohort it will be related to occupational exposures and smoking habits. Particular interest is in all cancers, especially respiratory and alimentary tract cancers. Radiological assessment of the cohort is also being carried out using the classification of chest radiographs developed by the International Labour Organization and the International Union Against Cancer.
SUPPORTED BY (No Supporting Organization Reported) funds n.a.

2.1712,
HEALTH OF FORMER THORIUM WORKERS
A.P. Polednak, Argonne National Lab., Biological & Medical Research Division, *9700 S. Cass Ave., Argonne, Illinois* 60439 (D-IARC-79-798)
The study population is comprised of about 4000 persons (mostly males) who worked at a thorium processing plant from the mid 1930's until 1973. Mortality and causes of death (from death certificates) are being studied with internal comparisons (by job classification and length of employment) and external comparisons (using U.S. mortality rates specific for sex, age, time and cause). For morbidity studies, subgroup of 558 males (who worked for one year or longer in jobs probably involving highest exposure levels to thorium) has been selected, and questionnaires on medical and occupational history, respiratory symptoms and personal habits (smoking and alcohol consumption) have been sent to those not known to be dead. A random sample of 100 of these 558 men has been selected for a pilot study which involves measurement of radioactivity levels, and a medical examination (including pulmonary function tests). Interest in the health of thorium workers stems mainly from the potential importance of thorium as an energy source. Lung cancer and other lung diseases (e.g., pneumonoconiosis) are of particular interest in these studies, since the major hazard involved in the thorium extraction process is believed to be related to inhalation of airborne thorium and thorium daughter products.

ATLANTA CANCER SURVEILLANCE CENTER

M.A. Child, Emory University, School of Medicine, Dept. of Preventive Medicine & Community Health, *1364 Clifton Rd. N.E., Atlanta, Georgia* 30322 (D-IARC-79-777)

The Atlanta Registry is one of eleven of such programs funded and sponsored by the National Cancer Institute of the United States. Each represents a unique set of persons with respect to climate, race, industrialization, lifestyles, and heritage. Atlanta represents a growing but not particularly industrialized city in the southeastern USA with a large black population and whose longtime resident white population is largely Anglo-Saxon. The study's overall objective is registration and follow-up of every case of cancer in the Atlanta Standard Metropolitan Statistical Area and a separate ten county rural area whose population is largely black. Patients are identified through hospital medical record departments, pathology laboratories, radiotherapy facilities, and death certificates. Collected by specially trained abstractors are demographic information, birthplace, census tract of residence, occupation, use of tobacco, alcohol, and medications, site and histological type of malignancy, diagnostic tests and procedures employed, extent of disease at diagnosis, therapeutic procedures undertaken including surgery, radiotherapy, chemotherapy, and immunotherapy, concomitant diagnoses, family history of cancer and the name of the physician following the patient's progress. Patients are followed through re-admissions to hospitals, by information from the follow-up physician, and through death certificates. It is hoped that these data will identify persons at unusually high or low risk of cancer through various factors of environment and background. Because the registry is population-based, it will be able to produce incidence data and patterns of diagnostic and therapeutic care for the area. Survival information will be calculated and the effectiveness of different modes of therapy evaluated. Cooperation with national and international special studies such as the relationship of non-melanotic skin cancer to the environment, of bladder cancer to the use of saccharin and other dietetic or occupational hazards.

PROSPECTIVE AND RETROSPECTIVE STUDY OF THE POSSIBLE RELATIONSHIP BETWEEN HERPESVIRUS TYPE II INFECTION AND GENITAL CANCER

Z.M. Naib, Emory University, School of Medicine, Dept. of Pathology, *1364 Clifton Rd. N.E., Atlanta, Georgia* 30322 (D-IARC-79-780)

Since 1964, more than 1,500 women were detected during routine cytological screening as having herpesvirus infection. These individuals are followed clinically and cytologically in a special herpes clinic: the incidence of cervical cancer was found to be approximately 10 times higher than in general populations cytologically screened. The main objectives of this study are to investigate the degree of this association and explain the nature of the association and related factors. The incidence of anaplasia was found to be higher in patients with primary herpesvirus type II infection.

THE JOHNS HOPKINS LUNG PROJECT FOR THE EARLY DETECTION, LOCALIZATION AND THERAPY OF LUNG CANCER

J.K. Frost, Johns Hopkins University, School of Medicine, Dept. of Cytopathology, *725 N. Wolfe St., Baltimore, Maryland* 21205

This study began in 1969 when the Johns Hopkins Medical Institution was asked to (1) develop improved methods for the cytological detection of lung cancer, (2) develop improved methods for the localization of lung cancers that are not detectable by chest X-rays, and (3) test these screening techniques in a population sample. The procedures which evolved are now being employed in Phase II of The Johns Hopkins Lung Project and by the other two centers in the Early Lung Cancer Cooperative Study - The Memorial Sloan-Kettering Hospital for Cancer, and Mayo Foundation. The three collaborating centers are assisted in uniform data collection and analysis by the University of Cincinnati. The goal of the cooperative study is to determine the effect of early cytological or X-ray detection, followed by surgical therapy, on long-term survival in lung cancer, as measured by lung cancer mortality in the survey populations. The Johns Hopkins Lung Project has recruited 10,390 male smokers, aged 45 or over, from the Baltimore metropolitan community. Volunteers were randomized into (a) a group screened by annual chest X-ray, and (b) a group screened by sputum cytology in addition to their annual chest X-ray. All chest X-ray examinations include independent double reading. In addition, all sputum cytology screenees receive an annual examination of an aerosol-induced sputum specimen plus an examination of mailed morning sputum every four months. Subjects in whom cancer is detected may be admitted to the Johns Hopkins Hospital for localization and therapy. Curative resection is undertaken where possible, otherwise therapy includes chemotherapy and radiotherapy. All ten thousand subjects will be followed for at least five years to determine survivorship or cause of death.

2.1716,

EPIDEMIOLOGY OF ACUTE LEUKEMIA IN URBAN CHILDREN

L. Gordis, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Epidemiology, *615 N. Wolfe St., Baltimore, Maryland* 21205 (D-IARC-78-661)

The epidemiological patterns of white children with acute leukemia are markedly different from those of black children. For example, a peak around ages 3-4 in mortality rates from acute leukemia has been known to exist in white U.S. children for about 30 years, but seems only recently to be developing in black children. This study is therefore examining the overall epidemiological patterns of acute leukemia in white and black children. In the first phase, records of all patients under 20 years of age discharged from metropolitan Baltimore hospitals from 1960-75 with a diagnosis of acute leukemia were reviewed. A death certificate search was also carried out to identify any cases which might not have been ascertained through hospital record review. The most important finding of this phase of study, already reported (Szklo, M. et al.: Am. J. Epidemiol. 104:330-331, 1976), was a marked increase over time of acute non-lymphocytic leukemia incidence rates in black children. In the second phase of the project, now under way, children with acute leukemia will be compared to two control groups, children with other malignancies and children without cancer, in order to determine whether cases differ from controls in terms of host and environmental characteristics and whether families of cases differ from control families in blood group distribution, immunoglobulin levels and prior experience of viral infections. Because of the small number of black children with acute leukemia in Baltimore, one Washington, D.C. hospital and two Philadelphia hospitals were also included in the case-control phase of the study.

EPIDEMIOLOGICAL STUDIES OF ENVIRONMENTAL POLLUTANTS IN RELATION TO REGULATIONS

J.M. Goldsmith, State Epidemiological Studies Lab., *2151 Berkeley Way, Berkeley, California* 94704 (D-IARC-79-708)

Data from large-scale occupational mortality studies are being collected and analyzed with special attention to the convergence of evidence indicating that specific occupations have excessive risks of cancer at certain sites. Indices for integration of studies showing epidemiological evidence of carcinogenicity with laboratory studies, including those reflecting mutagenicity, are being developed. Data on environmental exposure-effect relationships, especially community air pollutants, are being collected and analyzed. Data on carcinogenic agents for which workplace exposures are not yet regulated are also being collected, and regulations for arsenic, coal tar, and aminotriazole proposed.

MORTALITY AMONG U.S. VETERINARIANS

A.E. Blair, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., *9000 Rockville Pike, Bethesda, Maryland* 20205 (D-IARC-79-839)

Although transmission of oncogenic viruses from animals to humans has not been clearly demonstrated, this hypothesis continues to receive considerable support as this transmission may be a possible factor in the development of neoplasms. Veterinarians represent a group likely to experience exposure to animals with viral diseases as well as to chemicals and drugs. Using the obituary notices listed in the Journal of the American Veterinary Medical Association, the distribution of the causes of death among 5,000 veterinarians will be compared with an expected distribution derived from national and local populations. Classification of veterinarians by type of practice will help identify high risk groups.

CANCER MORTALITY AMONG PETROCHEMICAL WORKERS

P. Decouffe, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., *9000 Rockville Pike, Bethesda, Maryland* 20205 (D-IARC-79-846)

The objective of this study is to determine whether persons employed in the petrochemical industry experience unusual patterns of cancer mortality indicative of exposure to hazards in the work environment. The study group material consists of approximately 18,000 deaths among members of a labor union that represents a large segment of the petrochemical industry in the USA. Deaths among active union members have been reported to the central office of the union by the individual local branches since the 1940's. A proportionate mortality analysis will be performed to compare the relative frequencies of deaths from specific forms of cancer among union members with the experience of the general population. Occupational information for each subject includes date of entry into union and specific industrial category of the plant in which he worked. The investigation is intended to identify high-risk areas within the petrochemical industry that warrant further examination by more refined epidemiological methods.

SUPPORTED BY (No Supporting Organization Reported) funds n.a.

CANCER MORTALITY AMONG STRUCTURAL PEST CONTROL WORKERS

A.E. Blair, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., *9000 Rockville Pike, Bethesda, Maryland* 20205 (D-IARC-79-844)

The objective of the study is to determine whether persons applying various kinds of pesticides in non-agricultural settings experience unusual mortality patterns for cancer at specific sites that may be indicative of exposure to carcinogenic agents. The study group consists of approximately 5,000 persons who were employed by pest control firms in the state of Florida in 1965. The cohort will be followed for mortality to the present time and its site-specific cancer mortality rates will be compared to the general population of the area. Duration of employment and time since first employment in the trade will be considered in the analysis. Information on type of pest control work and general classes of pesticides used is also available.

DIETHYLSTILBESTROL-ADENOSIS PROJECT - GENITAL TRACT ANOMALIES AND CANCER IN FEMALES EXPOSED IN UTERO (ABBREV)

S.J. Robboy, Massachusetts General Hospital, Dept. of Pathology, *32 Fruit St., Boston, Massachusetts* 02114 (D-IARC-79-871)

Young women exposed in utero to diethylstilbestrol are known to be at risk for the development of clear cell adenocarcinoma of the vagina and cervix. A large proportion of the exposed population is also known to have developed adenosis of the vagina, extropion of the cervix, and variety of structural anomalies of the cervix and vagina, which have been described as ridges, rims, hoods or pseudopolyps. There is speculation that those women are also at a higher risk for the development of squamous cell dysplasia and carcinoma. The goal of this prospective study is to investigate the incidence and natural history of the above lesions. One thousand exposed women were identified through review of prenatal records, physician referrals and patients who presented themselves for examination. Controls for the cohort of subjects identified through review of prenatal records comprise a similar but non-exposed cohort. All subjects were examined initially in 1974-76 and will be re-examined at yearly intervals for a minimum of five years.

CORRELATION OF EPIDEMIOLOGICAL AND METABOLIC PARAMETERS - THE POSSIBLE ROLE OF VITAMIN A IN CERVICAL TISSUE EPITHELIUM

S.L. Romney, Yeshiva University, Bronx Campus, Albert Einstein School of Medicine, Dept. of Obstetrics & Gynecology, *1300 Morris Park Ave., Bronx, New York* 10461 (D-IARC-78-713)

In this study of carcinoma of the uterine cervix the primary focus is on the possible interrelationships of diet, with emphasis upon Vitamin A, social, environmental, epidemiological factors, and the cellular changes which are detectable clinically by routine cytology and biopsy of the uterine cervix. The availability of the Papanicolau test permits screening of large population groups and the finding of a positive or suspicious smear identifies 'women at risk'. Such women are being studied intensively in terms of (1) diet, with computer coding and scoring of nutrient values: (2) ethnic and socioeconomic background and (3) personal life-styles including educational performance as well as (4) measurements of specific blood and tissue biochemical levels and assessement of tissue pathology.

EPIDEMIOLOGY OF CANCER OF THE TESTIS IN UPSTATE NEW YORK

S. Graham, State University of New York, Buffalo Campus, School of Social Science & Admin., Dept. of Sociology/Social & Preventive Medicine, *3435 Main St., Buffalo, New York* 14214

The literature on cancer of the testis suggests a number of hypotheses dealing with possible relationships with cryptorchidism, occupational activity, clothing styles, sexual behavior, fertility, exposure to high temperatures, and the like. In our earlier demographic study of testis cancer it was found that the risk of testicular cancer was increased for persons who were in professional occupations, of several generations in this country, were rural or suburban dwellers, and had married early. We planned to interview all testis cancer cases from Upstate New York, beginning in autumn 1977. Names of cases will be made available to us as they are reported to the New York State Tumor Registry. To control for the fact that cancer of the testis appears to be a disease of high socioeconomic status, controls, matched on age (within 5 years), who reside in the neighborhoods of cases will be interviewed. It is anticipated that approximately 100 cases will be reported each year. Thus, in 3 or 4 years sufficient cases and neighborhood controls will be available for a definitive analysis. Data collection is under way. We have completed 76 case and 43 neighborhood control interviews.

OCCUPATIONAL LUNG CANCER IN THE RUBBER INDUSTRY

D.A. Andjelkovich, University of North Carolina, Chapel Hill Campus, School of Public Health, Dept. of Epidemiology, *Rosenau Hall, 201H, Chapel Hill, North Carolina* 27514 (D-IARC-79-969)

This study was prompted by conflicting findings in relation to occupational lung cancer in the industry. While an overall excess of lung cancer was found in Great Britain, an overall deficit was observed by us in the U.S. Accordingly, it was decided to investigate the relationship between mortality from this disease and specific occupational exposures. The main objective of this study is to identify, retrospectively, specific groups of workers who may experience an excess risk of mortality from lung cancer. In addition, the British report of an association between this disease and employment in areas where curing of green rubber products is performed is being evaluated and other published findings on a relationship between lung cancer and work in jobs involving compounding and mixing of raw rubber stocks is being examined. A case-control study design with over 100 cases and 400 controls is being used, matched on pertinent variables to eliminate confounding factors unique to occupational studies. The analysis involves examination of detailed employment records to determine whether cases were more likely to have worked in specific areas within the plant under study, which may now contain (or which may have contained in the past) respiratory system carcinogens. The design also includes an examination of certain non-occupational factors which may be responsible for the observed excess.

STOMACH CANCER AMONG RUBBER WORKERS - A CASE-CONTROL STUDY

S.B. Blum, University of North Carolina, Chapel Hill Campus, School of Public Health, Occupational Health Studies Group, *Rosenau Hall, 201H, Chapel Hill, North Carolina* 27514 (D-IARC-79-970)

Whereas the incidence of stomach cancer has been steadily declining in the U.S. during the past few decades, our analyses have indicated that rubber workers remain at a considerably higher risk than the general population. Because of the diverse chemicals to which these workers are being exposed, many of which are known or suspected carcinogens, an analytical study is being conducted to determine whether this excess risk may be caused by industrial exposures to polycyclic hydrocarbons, nitrosamines, asbestos, or carbon black. All of these substances have been, or are being, used or generated by the industrial processes in the rubber industry.

LEUKEMIA IN RUBBER WORKERS, A CASE-CONTROL STUDY

H.A. Tyroler, University of North Carolina, Chapel Hill Campus, School of Public Health, Dept. of Epidemiology, *Rosenau Hall, 201H, Chapel Hill, North Carolina* 27514 (D-IARC-79-974)

Recent descriptive mortality analyses in five major U.S. rubber companies have demonstrated a consist-

ent excess of deaths from malignant neoplasms of the lymphatic and haematopoietic system (LHS) among rubber workers. A preliminary case-control study has demonstrated an association between lymphatic leukaemia and a history of having worked in jobs entailing solvent exposure. An estimated 150 persons, dying in the period 1964-1973 with an LHS neoplasm, will be individually matched with two pairs of controls, who are to be selected from among non-cases within the source population from which the case derives. Complete work history information will be utilized for all study subjects. Analysis of case-control differences in work history will examine 1) the association of leukaemia, and of non-leukaemia LHS neoplasms, with solvent exposure, 2) the association of any LHS neoplasm with possibly carcinogenic factors within the work environment.

PESTICIDE MANUFACTURER/FORMULATOR MORTALITY STUDY

B.W. Carnow, University of Illinois, Medical Center at Chicago, School of Public Health, Dept. of Occupational & Environmental Medicine, *Box 4348, Chicago, Illinois* 60680 (D-IARC-79-803)

This study is seeking to determine if selected groups of workers in the pesticide manufacturing/formulating industry experience excess cause-specific mortality. Although a number of epidemiological studies have been carried out to examine the relationships between chronic pesticide exposure and morbidity and mortality, most have not included sufficient population numbers, length of exposure and latency periods in the study design. A cohort of approximately 4,000 workers who were employed in the pesticide manufacturing/formulating industry for a minimum of 12 months prior to 1980 will be studied and their mortality experience will be compared to that of the general population for 60 causes of death. In addition, attention will be directed to various categories of malignant and non malignant lesions specifically associated with exposure to organo-chlorine pesticides. A prospective cohort of workers in the pesticide industry will also be identified.

INVESTIGATION OF THE RELATIONSHIP OF GLUCOSE INTOLERANCE AND CANCER

J.A. Kautz, Northwestern University, Chicago Campus, School of Medicine, Dept. of Health & Preventive Medicine, *303 E. Chicago Ave., Chicago, Illinois* 60611 (D-IARC-78-740)

Data on four cohorts of employed persons in Chicago under study by Dr. Stamler for the past two decades are being used both for pilot studies, for more extensive epidemiological studies, and for examining the relationship of multiple factors to cancer mortality. Extensive data are available on these groups, in terms of factors possibly of epidemiological significance for the major cancers (particularly lung and colon cancer in men and breast and cervical cancer in women). This study investigates the relationship of diabetes and cancer in the population.

IDENTIFICATION OF HIGH RISK FACTORS IN THE AETIOLOGY OF BREAST CANCER

W.D. Shorey, Rush Presbyterian St. Lukes Medical Center, Dept. of Surgery, *1753 W. Congress Pkwy., Professional Bldg. 907, Chicago, Illinois* 60612 (D-IARC-79-810)

Certain epidemiological indices for the development of breast carcinoma have been developed in the past decade. These include race, family history, age at menarche, parity and age at first parity, previous benign breast lesions and the pathology found. These indices, and others, are being studied in four groups of patients: (1) Women who have developed breast cancer without previous breast disease; (2) women developing breast cancer after a previous benign biopsy; (3) women who have not developed breast cancer but have had single or multiple benign breast biopsies, and (4) women who have been examined at their place of employment and show no evidence of breast cancer.

MORTALITY AND INDUSTRIAL HYGIENE STUDY OF PCE WORKERS

D.P. Brown, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

Perchloroethylene (PCE) is used extensively throughout the dry cleaning industry (100,000 workers). Tests for carcinogenicity in the Bioassay Program of the National Cancer Inst. show an increase in hepatocellular carcinomas in mice. To date, the effects on humans from long-term low level exposure to PCE are unknown, and the study will assess these by analysis of cause-specific mortality among an identified group of dry cleaning workers. A cause of death for each individual in the cohort will be determined retrospectively and the observed deaths will be compared to those expected based on a standard race-, sex- and age-specific population. Worker exposure to PCE in the dry cleaning industry will be characterized by industrial hygiene surveys. The Stanford Research Inst. (SRI) is conducting the mortality study under contract. Personnel records from four labor unions have been used to assemble a cohort of approximately 1,659 dry cleaning workers who were employed for at least one year prior to 1960 in a facility where the primary solvent was PCE. All of the demographic and work history coding has been completed and vital status follow-up through the Social Security Administration (SSA) has been accomplished. Once the SSA data is processed, it will be determined how much more vital status follow-up is necessary. Industrial hygiene surveys have been conducted in 30 dry cleaning facilities in San Francisco, Oakland, Detroit and Cincinnati. An additional 15-20 surveys are planned in New York City and Chicago, and a final report will be ready in early 1980.

2.1739,

MORTALITY, MEDICAL, AND INDUSTRIAL HYGIENE STUDY OF PCB

D.P. Brown, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Biometry Section, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (D-IARC-79-985)

Polychlorinated biphenyls (PCB) are a class of chlorinated aromatic hydrocarbons that are widespread in the environment, are highly stable, and tend to concentrate in the food chain. Current use is primarily limited to the electrical industry as insulating material in capacitors and transformers. Reports of adverse health effects in humans and animals accidently exposed to PCB and the demonstration of carcinogenic effects of certain PCB in animals necessitate evaluation of the toxicology of these compounds. In humans the syndromes of chloracne and Yusho neonatorum have been extensively documented, in addition to gastrointestinal, endocrinological, haematological, and embryotoxic effects. The health effects of PCB exposure are being assessed by (1) retrospective mortality study of a cohort of occupationally exposed workers; (2) a cross-sectional medical survey of a cohort of currently employed workers; and (3) a detailed industrial hygiene survey. The mortality study is well under way; follow-up is near completion on the two study cohorts exposed to PCB. Several of the medical surveys have been completed. The industrial hygiene surveys of all plants included in the mortality study and medical study have been completed.

MORTALITY STUDY OF PESTICIDE FORMULATORS/MANUFACTURERS

D.P. Brown, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Biometry Section, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (D-IARC-79-986)

Pesticide formulators/manufacturers have been studied by numerous investigators. To date, there have been no reported retrospective mortality studies on sufficiently large cohorts of workers exposed to high levels of pesticides to yield definitive information on chronic long-term effects. Published studies do suggest, however, that chronic exposure and long latency may result in cancer, kidney and liver disease, suicides, accidents, diseases related to hypertension, and abnormalities in offspring. Any of these diseases may be attributable to a single pesticide or class of pesticides. Workers in this industry traditionally manufacture, dilute, mix, and package a large variety of pesticides and diluents, which change from season to season and from year to year depending on demand. The aim of this study is to determine if selected groups of pesticide formulators/manufacturers experience excessive cause-specific mortality. Records of several plants have now been microfilmed.

EPIDEMIOLOGICAL AND INDUSTRIAL HYGIENE STUDIES OF THE FOUNDRY INDUSTRY

E.A. Egan, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Biometry Section, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (D-IARC-79-991)

In order to ascertain which health problems may be associated with employment in a foundry, a proportional mortality study is being conducted. The International Molders and Allied Workers Union has provided the National Institute for Occupational Safety and Health with data on 3,243 of its members who died between June 1, 1971, and December 31, 1975. Death certificates have been obtained for the majority of the study population. Statistical analyses will take into account length of employment and geographical location of the deceased workers in the study population. Studies conducted on foundry workers in both Finland and Canada found that workers employed in this industry have an increased risk of lung cancer. Neither of the industrial hygiene studies performed in conjunction with the Finnish and Canadian epidemiological studies was successful in identifying the chemical or physical agent(s) that may have been responsible for the increased lung cancer incidence. It is thus planned to initiate an industrial hygiene study to evaluate job areas or processes with potential for exposure to known or suspected carcinogens.

2.1743,

COMPARISONS OF OCCURRENCE AND LEVELS OF DRINKING WATER CONSTITUENTS AMONG PAIRS OF HIGH AND LOW CANCER MORTALITY COUNTIES IN OHIO

D.G. Greathouse, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., *5555 Ridge Ave., Cincinnati, Ohio* 45268 (D-IARC-79-992)

The basic study procedures and goals of this project are similar to those of the national study. As a result of at least two independent epidemiological studies attention has been focused on Ohio because of the high cancer mortality rates for counties supplied with drinking water from surface sources. Since Ohio counties represent wide contrasts in water sources, geology, industrialization, socioeconomic levels, and cancer mortality rates, it was judged that a study limited to Ohio would be worthwhile. The selection of study counties will be based on the county mortality data available from Ohio State University and the industrial data available from the Ohio Environmental Protection Agency and various publications.

SUPPORTED BY (No Supporting Organization Reported) funds n.a.

2.1744,

COMPARISONS OF OCCURRENCE AND LEVELS OF DRINKING WATER CONSTITUENTS BETWEEN 12 MATCHED PAIRS OF HIGH AND LOW CANCER MORTALITY COUNTIES

D.G. Greathouse, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., *5555 Ridge Ave., Cincinnati, Ohio* 45268 (D-IARC-79-993)

Using available data from the National Cancer Institute, all U.S. metropolitan counties were sorted into categories defined by five parameters - region of the country, population years at risk (females for the time period 1968-;972), percent of population employed in manufacturing industry, percent urbanization, and average educational level. Each pair of counties was selected from categories so that one had a female age-adjusted cancer mortality rate 24 and the other 16 for the total of four sites, namely colon, rectum, bladder, and liver. Historical data from each county have been collected from the appropriate state regulatory agencies and the major utilities in the counties; data collected are sources and treatment technologies used during the previous 30 years for each served area. Waters samples are being collected bimonthly for analyses for mutagens and biannually for analyses for 41 inorganic chemicals, 6 trihalomethanes, TOC, fluorescence, asbestos, and radiation. Comparisons of water constituent occurrences and levels, treatment technologies, and source types will be made between the pairs of counties to determine if there are significant differences between counties with contrasting cancer mortality rates.

2.1745,

MORTALITY, MEDICAL, AND INDUSTRIAL HYGIENE STUDIES OF CHLORINATED HYDROCARBONS

T.J. Meinhardt, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Biometry Section, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (D-IARC-79-997)

Information from various test systems has been interpreted to indicate that chlorinated hydrocarbons, benzyl chloride, monochlorobenzene, methylene chloride and methyl chloride, are being investigated for epidemiological study. In conjunction with industrial hygiene surveys under contract, the National Institute for Occupational Safety and Health is determining the feasibility of conducting a mortality study on one or more of these four chemicals. The possibility of doing such a study will, in a large part, be determined by the existence of a sizable exposed worker population and appropriate personnel records. It has been found that it is not practical to study benzyl chloride because few workers are or have been exposed; also because adequate records on past workers are not available. An industrial hygiene study has been conducted in a cross-section of the industry to document patterns of current exposure to this chemical. The feasibility of doing epidemiological studies on workers exposed to the other three chemicals is currently being determined.

2.1746,

MORTALITY AND INDUSTRIAL HYGIENE STUDIES OF PRINTING TRADES

G.O. Ness, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Biometry Section, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (D-IARC-79-998)

Published literature on the printing trades suggests that a significant number of health hazards exist. Workers are exposed to a variety of substances, i.e., carbon black, oil mist, polychlorinated biphenyls, polyvinyl chloride, and carbon disulphide. Increased risk of cancer of the skin, lung, digestive system and bladder has been suggested. Other suspected sequelae include heart disease, acro-osteolysis and liver cirrhosis. A detailed characterization, including industrial hygiene assessment of the industry, and a retrospective study of the mortality patterns among select specialities within the printing trades industry are being conducted under contract. The contractor, Mt. Sinai Hospital, New York City, has performed industrial hygiene surveys and industrial studies in selected printing establishments. Records from a printing union local have been collected and are being analyzed.

2.1747,

MORTALITY AND INDUSTRIAL HYGIENE STUDY OF CLAY FIBER WORKERS

G.O. Ness, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Biometry Section, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (D-IARC-79-999)

In the process of studying the chronic health hazards of occupational exposure to respirable fibers such as asbestos, glass fibre, and mineral wool, the National Institute for Occupational Safety and Health (NIOSH) has identified additional fibrous minerals which are of occupational health concern. Attapulgite, one of a group of substances collectively known as 'fuller's earth', is a mineral fiber which has been discussed in relation to chronic lung disease. A mortality study of a population with an occupational exposure to attapulgite for approximately 30 years since the beginning of exposure is being conducted. This will permit investigation of long-term chronic health effects of exposures to small diameter, short mineral fibers by study population with sufficient latency. To date 85% of the present and past work force has been followed up.

SUPPORTED BY (No Supporting Organization Reported) funds n.a.

2.1748,

MORTALITY STUDY OF WORKERS EXPOSED TO SMALL FIBROUS GLASS

G.O. Ness, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Biometry Section, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (D-IARC-79-1000)

A recently completed study of fibrous glass workers at a plant in Ohio failed to demonstrate any increased mortality due to malignant respiratory disease. However, increased mortality due to non-malignant respiratory disease was noted in the same study population. The observed lack of an excess mortality due to malignant respiratory disease in this population may have resulted from bias in study selection. The major portion of the study group was exposed to fibres of large diameter, which generally have not been shown to be carcinogenic in man or animals. This study proposes a retrospective mortality study of a subcohort of the entire working population who were subjectively determined through a double-blind study to be exposed to fibres from one to three microns in diameter, a range suspected of having carcinogenic potential in man. This study, however, will not answer the question of carcinogenicity of fibres less than 1 micron in diameter.

SUPPORTED BY (No Supporting Organization Reported) funds n.a.

2.1749,

MORTALITY AND INDUSTRIAL HYGIENE STUDIES OF MINERAL WOOL WORKERS

G.O. Ness, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Biometry Section, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (D-IARC-79-1001)

In view of the demonstrated carcinogenicity of asbestos fibers, industries have begun searching for substitute materials. However, the fibers of these substitute materials may be similar in shape and size to those of asbestos. It is felt by many that the morphology of the fibers is the most important factor in the development of malignant and non-malignant respiratory disease. Since little is known of the health effects on man of these and other respirable fibers, it was felt appropriate to investigate this question by environmental surveys and cohort mortality studies. The presence of other substances that may promote the development of adverse health effects or act in a synergistic manner is also being examined. To date 85% of the study cohort has been followed-up. The coding of occupational histories and acquisition of death certificates are near completion and the industrial hygiene research has been completed.

2.1750,

LEUKEMIA IN BENZENE WORKERS

R.A. Rinsky, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Biometry Section, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (D-IARC-79-1002)

Workers occupationally exposed to benzene in 1940-1949 were followed to determine their vital status as of 1975. In comparison with two control populations, a significant (p less than 0.002) excess of leukemia was observed. A five-fold excess risk of all leukemias and a ten-fold excess of deaths from myeloid and monocytic leukemias combined. These figures may underestimate the true leukaemia risk to benzene-exposed workers, because follow-up is only 75% complete and the untraced 25% of the study population were all regarded in the analysis as being alive at the end of the study period. The environment of the workers in the study population was not contaminated with solvents other than benzene, and existing records indicate that the benzene levels themselves were generally below the limits recommended at the time of their measurement. Completion of follow-up of this cohort is continuing.

SUPPORTED BY (No Supporting Organization Reported) funds n.a.

2.1751,

MORTALITY AND INDUSTRIAL HYGIENE STUDIES OF WORKERS EXPOSED TO ETHYLENE OXIDE

R.A. Rinsky, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Biometry Section, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (D-IARC-79-1003)

Evidence exists indicating that ethylene oxide is a carcinogen and mutagen in animals. Industrial hygiene and mortality studies will be performed on a cohort of workers exposed to this agent. The mortality study will be conducted to determine whether or not an excess number of cancer deaths (or any other type of deaths) has occurred among deceased workers from the plant or plants being investigated. Detailed industrial hygiene studies will be conducted for the facilities included in the mortality study. Personal monitoring of workers' present exposure in selected job categories will be conducted at each facility. Attempts will be made to determine exposure levels in the past. Preliminary studies of manufacturing plants have been conducted. The results of these studies will be used in the development of a recommended safe exposure standard.

SUPPORTED BY (No Supporting Organization Reported) funds n.a.

2.1752,

RETROSPECTIVE COHORT MORTALITY STUDY OF WORKERS EMPLOYED IN THE NORTHWEST PAPER, PULP AND PLYWOOD INDUSTRIES

C.F. Robinson, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Biometry Section, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (D-IARC-79-1005)

A recent analysis of state vital statistics has suggested that persons working in the paper, pulp and plywood industries may be at particular risk of developing malignancies of the blood forming organs and lymph system. The purpose of this study is to examine the mortality experience of persons working in the Northwest paper, pulp and plywood industries, in particular, to assess whether employees in these industries have experienced an excess mortality from malignant diseases. Where the analysis suggests a cancer mortality excess, an attempt will be made to identify 'agents' or processes which are demonstrably associated with the increased mortality.

2.1753,

MORTALITY AND INDUSTRIAL HYGIENE STUDY OF WORKERS EXPOSED TO ACRYLONITRILE

C.F. Robinson, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Biometry Section, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (D-IARC-79-1006)

Acrylonitrile (AN) is a chemical intermediate widely used in the manufacture of acrylic fibre, synthetic rubbers and plastics. The results of a recent study conducted by the Manufacturing Chemists Association showed that rats fed acrylonitrile in their drinking water developed tumours at various sites. A preliminary report from an acrylic fibre production plant has indicated an excess of lung and colon cancer deaths occurring among workers assigned to polymerization areas. In order to further investigate these findings, an epidemiological evaluation of another cohort of workers exposed to acrylonitrile will be undertaken. An industrial hygiene survey will be conducted concurrently in order to document worker exposure levels, at present and in the past. A retrospective cohort analysis will be conducted on this cohort of workers who will have had sufficient latency to demonstrate any chronic effects of acrylonitrile exposure.

2.1755,

MORTALITY PATTERNS, 1940-1975, AMONG WORKERS EMPLOYED IN AN ASBESTOS TEXTILE, FRICTION AND PACKING PRODUCTS MANUFACTURING FACILITY

C.F. Robinson, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Div of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (D-IARC-79-1004)

A preliminary report of a study of a cohort of textile, friction, and packing products asbestos production workers exposed to 99 percent chrysotile asbestos (except during the war years) demonstrated an excess risk for nonmalignant respiratory disease, suicide, heart disease, respiratory tract cancer and mesothelioma of the pleura and peritoneum among males; and an excess risk for nonmalignant respiratory disease, respiratory tract cancer and mesothelioma of the pleura and peritoneum among females. An increased risk due to lymphosarcoma among male asbestos workers was also indicated. These findings once again lend support to the conclusion that occupational exposure to predominantly chrysotile asbestos poses a carcinogenic risk for malignancies of multiple sites. The preliminary report is now in the process of being prepared for final publication.

MORTALITY, REPRODUCTIVE, AND INDUSTRIAL HYGIENE STUDIES OF CARBON DISULPHIDE WORKERS

S.G. Selevan, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Biometry Section, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (D-IARC-79-1011)

Carbon disulphide is used in a variety of industries; it is used in the xanthenation of cellulose to produce viscose rayon and cellophane and as a solvent for sulphur chloride in vulcanizing rubber. Additional uses are as a solvent for rubber cement, phosphorus, fats, oils, resins, and waxes, as an insecticide and also in the manufacture of optical glass. The toxicity of carbon disulphide has been recognized for many years and it has been generally associated with central nervous system effects, such as loss of memory, excessive irritability, vertigo, melancholia and, in severe cases, dementia. More recent studies indicate an increased mortality and morbidity from cardiovascular diseases and effects on the reproductive systems of both men and women. A study of this agent conducted by the National Institute for Occupational Safety and Health has the following phases: (1) A mortality study under contract; (2) a study of mutagenesis by administering reproductive history questionnaires to wives of workers; (3) a cross-sectional study to investigate the adverse health effects in workers exposed to carbon disulphide, and (4) an industrial hygiene study to determine present carbon disulphide exposure levels and estimate working lifetime exposures.

2.1757,

MORTALITY, MEDICAL AND INDUSTRIAL HYGIENE STUDIES OF WORKERS EXPOSED TO SYNTHETIC ESTROGENS

S.G. Selevan, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Biometry Section, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (D-IARC-79-1012)

Synthetic estrogens are a group of synthetic hormones having serious potential effects on exposed workers. Women taking oral contraceptives have an increased risk of thromboembolism, cerebral vascular disease, and myocardial infarction. A study by the National Institute for Occupational Safety and Health (NIOSH) carried out in an oral contraceptive plant indicated that problems are occurring in both males (gynecomastia) and females (menstrual changes). Also, it has been noted that estrogens may be carcinogenic. A cross-sectional medical/environmental study is proposed to investigate health problems resulting from exposure to synthetic estrogens and to attempt to determine a safe level of exposure to these agents. A mortality study of workers occupationally exposed to oral contraceptives will be performed to determine if an excess number of carcinoma deaths have occurred in exposed workers.

A STUDY OF CANCER AND THE PUBLIC DRINKING WATER SUPPLIES IN MISSOURI

C. Marienfield, University of Missouri, Columbia Campus, School of Medicine, Dept. of Community Medicine, *M228 Medical Sciences, Columbia, Missouri* 65201 (D-IARC-79-892)

This project involves setting up a data base of mortality, morbidity, and environmental information for rural postal routes grouped into rural water supply areas. This technique permits comparison of cancer rates for water supply areas which differ considerably in terms of water quality, industrial exposures, geology, and socioeconomic characteristics. County units which are often used may not coincide with water utility service areas. This project should permit an evaluation of the health and environmental (primarily drinking water) consequences of existing or newly established industrial and/or mining operations within rural areas.

RETROSPECTIVE STUDY OF CANCER IN BLACK AND WHITE POPULATIONS

S. Albert, Michigan Cancer Foundation, Dept. of Biometry & Medical Sociology, *110 E. Warren St., Detroit, Michigan* 48201 (D-IARC-79-879)

It is recognized that certain cancers differ in white and black populations with respect to extent of disease at diagnosis and survival. The purpose of the present study is to characterize the 10 most frequent cancers in the black and white populations. The study is concerned with incidence, histological types, organ distribution (where applicable), extent of the disease at diagnosis, treatment and survival. These characteristics are being studied over a period of time, not less than years, to determine whether any changes have occurred. This study is also designed to determine whether Detroit is similar to other areas or whether there are regional differences.

GASTRIC CANCER IN SAN MARINO

C.E. Jackson, Henry Ford Hospital, Dept. of Medicine, *2799 W. Grand Blvd., Detroit, Michigan* 48202 (D-IARC-79-881)

The purpose of this project is to define the genetic and environmental factors causing the high frequency of gastric cancer observed in San Marino. Initial studies have revealed a higher percentage of patients with first degree relatives affected than in the controls. Screening of segments of the population by gastroscopy is being undertaken in attempts to detect the neoplasms early. The project is a cooperative one between physicians in San Marino and in Detroit, Michigan, USA which has a large San Marinese population.

THE EPIDEMIOLOGY OF MULTIPLE MYELOMA

S. Grufferman, Duke University, School of Medicine, Dept. of Pediatrics, *Box 3711, Durham, North Carolina* 27710 (D-IARC-79-977)

The major objective of this case-control study is to learn more about the epidemiology of multiple myeloma. Surprisingly little is known about the epidemiology of this disease, available information is dated, and there are few aetiological hypotheses. The study will have two major components: a medical record review of 450 multiple myeloma cases and an interview study of an additional 150 patients, both components involving matched hospital controls. In addition to seeking associations with available demographic variables, associations between multiple myeloma and socioeconomic class, occupation, environmental exposures, diet, and diseases causing 'immune stimulation' will be evaluated. Particular attention will be paid to evaluation of the association between socioeconomic class and multiple myeloma. Paradoxically, multiple myeloma is reported as being positively associated with high socioeconomic class whereas incidence rates are twice as high in blacks as in whites.

CAUSES OF DEATH OF ANESTHETISTS FROM THE CHLOROFORM ERA

H. Linde, Northwestern University, Evanston Campus, School of Medicine, Dept. of Anesthesia, *633 Clark St., Evanston, Illinois* 60201 (D-IARC-79-812)

The mortality rates of physicians who gave anesthetics during the period when chloroform was in use will be studied to ascertain if there were excessive deaths due to cancer. Anesthetists will be identified who died prior to 1947 (the date when previous

study of causes of death among anesthetists started) and their causes of death obtained. The rates for these causes will be compared with those observed in the periods 1947-1956, 1957-1966, 1967-1972. The literature and historical records will also be studied to arrive at an estimate of the use of chloroform in American anesthetic practice during the earlier part of this century.

REASONS FOR VARIATIONS IN CANCER PATIENT SURVIVAL BY RACE
L.N. Kolonel, University of Hawaii System, Manoa Campus, School of Public Health, Dept. of Biomedical Sciences, *Spalding Hall, Room 255, Honolulu, Hawaii* 96822 (D-IARC-79-789)
This study is examining ethno-racial variations in cancer patient survival for four sites of cancer: stomach, colon and rectum, breast and lung. Five ethnic groups are included: Caucasian, Japanese, Chinese, Filipino and Hawaiian. Data are from the Hawaii Tumor Registry, and survival rates by race are being compared after adjusting for extent of disease at diagnosis. Further analyses will use socio-economic indicators developed from registry and census data in a first attempt to explain any observed racial differences in survival.

CLINICAL CANCER GENETICS
L.C. Strong, University of Texas, Health Science Center at Houston, Graduate School of Biomedical Sciences, Section of Medical Genetics, *P.O. Box 20334, Houston, Texas* 77025 (D-IARC-79-1054)
The objectives of this study are to identify unusual familial aggregations of childhood cancers, associations of childhood cancer and congenital anomalies, or the occurrence of rare tumours in childhood for further aetiological study. Patients are referred from clinical departments. All cancers or other disorders in families under study are documented by medical records and/or vital statistics. Documented familial cases are compared with nonfamilial cancer cases with respect to age at onset, anatomical site, multiplicity of cancers, congenital and chromosomal abnormalities or other predisposing conditions. Within affected families, various clinical and genetic markers are being evaluated.

GENETIC CONSEQUENCES OF CHILDHOOD CANCER
L.C. Strong, University of Texas, Health Science Center at Houston, Graduate School of Biomedical Sciences, Section of Medical Genetics, *P.O. Box 20334, Houston, Texas* 77025 (D-IARC-79-1055)
The objective of this study is to identify genetic effects of cancer and therapy including both the primary factors predisposing to cancer which may lead to subsequent tumours in the patient or heritable tumours in offspring, and treatment-induced mutations which may lead to subsequent tumours or heritable disease in the offspring of patients who have had childhood cancers. A registry of long-term survivors of childhood cancer and their offspring is being established, including data concerning congenital anomalies, predisposing conditions, family history, primary cancer treatment, and other medical or social history. Multiple factorial analysis of risk factors of second tumours and of genetic disease in the offspring will be undertaken.

CANCER, ALCOHOL AND SMOKING
G.N. Schrauzer, University of California, San Diego Campus, Graduate School, Dept. of Chemistry, *P.O. Box 109, La Jolla, California* 92037 (D-IARC-78-844)
Comprehesive statistical study of the role of alcohol and smoking in the causation of cancer is under way.
SUPPORTED BY (No Supporting Organization Reported) funds n.a.

2.1768,
CASE-CONTROL STUDY OF EPITHELIAL OVARIAN CANCER IN WOMEN AGES 25 TO 49
J.T. Casagrande, University of Southern California, School of Medicine, Dept. of Community & Family Medicine, *2025 Zonal Ave., Los Angeles, California* 90033 (D-IARC-78-849)
Ovarian cancer has many epidemiological similarities to breast cancer but until quite recently has received little attention from epidemiologists. Daughters of breast cancer patients have an increased risk of breast cancer and have major differences in their hormone levels compared to other comparably aged girls. (Daughters were used instead of breast cancer patients since the hormone levels which presumably established the patients' risk earlier in life may not be reflected in their levels at diagnosis and these levels may also be altered by the disease itself). A similar approach has been adopted for ovarian cancer and the objectives of the present study are to 1) investigate further the risk factors associated with ovarian cancer, 2) determine whether the family members of patients also have an increased risk of developing ovarian cancer, and 3) identify the teenage daughters of patients and controls for future hormone studies. The present study consists of the microscopically confirmed ovarian cancers of epithelial origin in white women aged 25-49 diagnosed in Los Angeles from 1973 to 1976. Each patient is to be matched with three controls: a high school friend, a family member and a randomly chosen neighbour.

2.1769,
RETROSPECTIVE STUDY OF ENDOMETRIAL CANCER AMONG SOUTHERN CALIFORNIA WOMEN
T.M. Mack, University of Southern California, School of Medicine, Dept. of Pathology, *2025 Zonal Ave., Los Angeles, California* 90033 (D-IARC-78-855)
The objective of this descriptive study of carcinoma of the endometrium is to test previously suggested causal hypotheses. Cases with endometrial cancer have been identified by the Los Angeles County University of Southern California Cancer Surveillance Program. Incidence rates for this cancer determined for specific sub-groups of the population have revealed a direct positive correlation with social class. The pathology reports for 2,500 white women aged 55 to 64 have been reviewed. A sample of tissue slides will be examined blindly by single pathologist to verify the diagnosis of the lesions and test whether a cancer-social class relationship can be demonstrated for invasive as well as non-invasive disease.

EPIDEMIOLOGY OF PANCREATIC CARCINOMA AND IDENTIFICATION OF HIGH-RISK GROUPS
T.M. Mack, University of Southern California, School of Medicine, Dept. of Pathology, *2025 Zonal Ave., Los Angeles, California* 90033 (D-IARC-78-856)
The objectives of this research are to study the epidemiology of cancer of the pancreas, to formulate causal hypotheses and identify groups at high risk of developing this tumour. A large case-control study, to be performed in Los Angeles County, has been designed to permit simultaneous examination of multiple antecedent risk factors. Cases with cancer of the pancreas will be identified by the Los Angeles County University of Southern California Cancer Surveillance Program. questionnaire has been designed to obtain data on occupational and on environmental exposures - tobacco and alcohol consumption, diet, and medical history and treatment. It will be administered to both cases and neighbourhood controls as soon as possible after the cases have been diagnosed. Standard matched pair analyses of multiple variables will be performed on the data from the questionnaire.

MALIGNANT MELNOMA - A CASE-CONTROL STUDY IN LOS ANGELES
T.M. Mack, University of Southern California, School of Medicine, Dept. of Pathology, *2025 Zonal Ave., Los Angeles, California* 90033 (D-IARC-78-858)
The annual incidence of malignant melanoma in Los Angeles is about 10 per 100,000 and appears to be increasing. A case-control study has been designed to test and formulate causal hypotheses and to identify groups at high risk. The specific aims of this study are: 1) To quantify the risk of persons for melanoma in relation to job, medical history and particular patterns of behavior, inheritance and skin characteristics, 2) To distinguish between the determinants of risk to different body sites and the determinants of different pathological types. Cases with malignant melanoma will be identified by the Los Angeles County University of Southern California Cancer Surveillance Program. A questionnaire designed to obtain data on occupational and environmental exposures, behavioral patterns in the sun, medical history and treatment, and skin features will be administered to both cases and controls. In addition, skin color will be determined for cases and controls.

WISCONSIN CANCER REPORTING SYSTEM - CANCER SURVEILLANCE AND RESEARCH
M.A. Woodbury, State Div. of Health, Section of Epidemiological Surveillance & Assessment, *State Office Bldg., Madison, Wisconsin* 53702 (D-IARC-79-1074)
The overall objective of the epidemiological study section of the Wisconsin Cancer Reporting System is the identification of high risk population groups, environmental factors and potential carcinogenic agents. This is a long-range plan currently directed toward developing the tools necessary for providing a mechanism for identifying cancer morbidity and mortality events or patterns significantly deviating from past trends. A computer program will be written to indicate such occurrences. Specific epidemiological studies will determine the factors involved, should the unusual event or pattern not be the result of changes in reporting habits. A computer program will also be developed to correlate an ongoing basis on various environmental conditions with cancer morbidity and mortality. (For example, a study of the degree of correlation of cancer mortality by distance from a taconite mine with measurements of asbestos in air, water and soil by distance from the mine). It is anticipated that such computerized surveillance will substantially increase the ability to recognize changes early and to set in action the analytical epidemiological studies required.

PHYSIOLOGICAL CORRELATES OF LEUKEMIA

D.E. Dix, Haynes Medical Lab., *26 Haynes St., Manchester, Connecticut* 06040 (D-IARC-79-751)

All tumors reported by the Connecticut Tumor Registry (Cancer Incidence in Five Continents, III, IARC No. 15, pp. 196-199, 1976), with the exception of chorionepithelioma, were divided into two classes. Class I tumors have a single peak incidence at age greater than 60: Class II tumors (lymphatic leukemia, bone, testis, and Hodgkin's) have two incidence peaks; one at age greater than 60, and one at age less than 35 with a peak height of 3 percent or more of the total incidence and a width of at least 20 years. All class I tumors have very similar incidence patterns reaching 25 percent, 50 percent, 80 percent of their total incidence between ages 42-74, 62-82, and 75-88, respectively. This similarity suggests a common cancer susceptibility factor. The study aims to identify characteristics of immune or endocrine status which correlate with this pattern of incidence. The early incidence peak of class II tumors suggests the expression of tumor specific susceptibility factors. Physiological properties which are unique to all class II tumors are being investigated with a focus on properties which distinguish acute lymphocytic leukemia, which belongs to class II, from acute and chronic myeloid leukemia as well as chronic lymphatic leukemia which belongs to class I.

EXPOSURE TO HALOGENATED ORGANIC CHEMICALS FROM DRINKING WATER

H. Enos, University of Miami, School of Medicine, Dept. of Epidemiology, *1400 N.W. 10th Ave., Box 520875, Coral Gables, Florida* 33152 (D-IARC-79-775)

A method for determining trihalomethanes in human blood has been developed. Animal models have been used to determine the sensitivity of the technique in assessing exposure to chloroform, carbon tetrachloride, trichloroethylene, bromodichloromethane and p-dichlorobenzene. A body burden survey of persons exposed to various levels of trihalomethanes in their drinking water is in progress. Persons living in the environs of Miami, Florida, having different levels of trihalomethanes in their drinking water are participants in the study. Each participants is interviewed and a blood sample drawn for trihalomethane level determination. So far levels of chloroform have been observed in all participants in the range of 10-60 parts per billion.

SURVEILLANCE OF CANCER MORBIDITY IN DULUTH, MINNESOTA

E.E. Sigurdson, State Dept. of Health, Chronic Disease Section, *717 Delaware St. S.E., Minneapolis, Minnesota* 55440 (D-IARC-79-887)

The study will monitor the incidence of cancer of all sites in the resident population of Duluth, Minnesota, during 1969-1981 or longer in order to detect any health effect from the ingestion of asbestiform fibres in the city water supply. Cases will be ascertained through hospital records at St. Luke's, St. Mary's and Miller-Dawn Hospitals in Duluth and at the Mayo Clinic. Rates will be compared with data from the Minneapolis-St. Paul Component of the Third National Cancer Survey and the Surveillance, Epidemiology and End Results Program of the U.S. National Cancer Institute. Additional information will be obtained from persons with cancer of selected sites and matched controls regarding length of residency in the city, smoking history, occupational and dietary history.

CONNECTICUT TUMOR REGISTRY - FORTY YEAR REPORT

J.F. Heston, Connecticut Cancer Epidemiology Unit, *30 College St., New Haven, Connecticut* 06510 (D-IARC-79-753)

A compilation of the incidence and mortality data of the Connecticut Tumor Registry (CTR), 1935-1974, is being prepared to make the data generally available. Because of the uniquely long history of the population-based CTR, its data are of particular value in the study of secular trends. Research workers make frequent use of the data in various combinations. The information will be presented in chapters. The initial chapter will describe the Registry briefly and will give technical information and general definitions needed to understand and use the data. The second chapter will include tables of incidence frequencies for about 40 specific cancer sites by single year of incidence starting in 1935, by sex and 5 year age group. Incidence rates will be presented similarly by 5 year time periods for the common cancers and by 10 year or possibly longer time periods for rare cancers. The third chapter will give information about cancer mortality in a format comparable to that for incidence. To the extent practicable, the format will be similar to that used for the Third National Cancer Survey. Subsequent chapters will be designed on the basis of experience gained from preparation and field testing of the first three.

COLORECTAL CANCER - FACTORS RELATED TO SURVIVAL

T.R. Holford, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510 (D-IARC-79-754)

Cancer of the colon and rectum is the second most frequently occurring cancer among women and the third among men in the United States, the median survival time being about 2.2 yrs and 2.0 yrs respectively. This project will investigate prognostic factors for survival from colorectal carcinoma using cases on file in the Connecticut Tumor Registry, which is a member of the Cancer Surveillance, Epidemiology and End Results (SEER) Group. Statistical methodology will be developed so that survival analysis with covariates can be done for cancer registry data. The analysis will simultaneously consider, using a regression-like approach, the effect of several factors on survival so that the interrelationships can be investigated. The variables of interest include age, race, sex, treatment, and extent of disease. In addition, information on socio-economic status, environmental factors, and associated lesions will be investigated to determine their effect on survival.

RADIATION AS A CAUSE OF BREAST CANCER WITH PARTICULAR REFERENCE TO ACNE TREATED WITH RADIATION AND TO MAMMOGRAPHY

N. Simon, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Radiation Research, *5th Ave. at E. 100th St., New York, New York* 10029 (D-IARC-79-954)

Women who have undergone previous radiotherapy for acne should be added to the group of radiation exposures previously known to cause breast cancer - young women fluoroscoped for tuberculosis, survivors of atomic bomb explosions and postpartum irradiated mastitis. Some 27 patients with cancer of the breast who were treated with irradiation previously for acne have been identified in our department. The number of women who have been treated with radiation for acne is now being investigated, to attempt to determine the incidence of cancer of the breast in such women. This survey of a population of women has been started as a feasibility study of 1,000 women in New York.

2.1784,

EVALUATION OF CARCINOGENIC AGENTS IN CIGARETTE SMOKE

E.L. Wynder, American Health Foundation Inc., Dept. of Epidemiology, *320 E. 43rd St., New York, New York* 10017 (D-IARC-79-962)

The objective of the study is to determine means of preventing diseases related to tobacco usage by identifying less hazardous smoking products and habits, and susceptible subjects, and to monitor the use of the new low tar cigarettes to determine characteristics of users toward predicting population at increased risk of disease. The effect of changes in tobacco products on risks for cancers of the respiratory, urinary, upper alimentary and biliary tracts and the pancreas will be measured. Questionnaires are administered to hospitalized patients between 20 and 80 years of age. Patients with tobacco-related diseases are designated as cases and are matched with patients with no present or previous tobacco-related disease (controls) by age, sex, case and hospital. The major parameters of tobacco usage investigated include (1) type, duration and amount of tobacco use by brand, (2) the 'tar' and nicotine content of cigarettes smoked, (3) type and frequency of filter use, (4) inhalation practices. These data are analyzed in relation to various demographic characteristics and risk ratios calculated. The study continues to substantiate earlier findings on reduced risk of disease for persons who smoke filter cigarettes for 10 years or more. Cancer risk according to 'tar' level is being analyzed. One of the fundamental purposes of

the study is to demonstrate and determine what the risk will be for individuals who have smoked low-tar and low-nicotine cigarettes for 15, 20, 25 years and, finally, for those who have smoked such cigarettes for their entire lifetime.

2.1785,

COLON CARCINOMA, DIET AND THE MICROFLORA

M.H. Floch, Norwalk Hospital, Gastrointestinal & Nutrition Laboratory, *24 Stevens St., Norwalk, Connecticut* 06856 (D-IARC-79-762)

Populations with a low incidence of cancer of the colon (African, Indian and Japanese) consume a low fat, high fiber diet and exhibit differences in their fecal microflora and fecal acid and neutral steroids excretion when compared to populations with a high incidence of colon cancer. This study is examining differences between these factors in patients with colon cancer, patients with cancer other than gastrointestinal, and control subjects, all from a population with a high incidence of colon cancer. The comparison of dietary factors obtained through dietary histories indicates no significant differences between the three groups. The predominant fecal flora of the colon cancer group shows an increase in aerobic bacteria compared with controls. No differences are observed with regard to species of the organisms. The comparison of the non-gastrointestinal cancer patients with controls also shows significant variations (decrease in total anaerobes and Eubacterium species). Total bile acid and neutral steroids excretion is not significantly different in the three groups. The colon cancer group does, however, excrete less lithocholic, coprostanol, and coprostanone compared to the control group. Final evaluation of follow-up medical data is presently being undertaken.

BENIGN ADENOMAS OF THE LIVER AND ORAL CONTRACEPTIVES

E. Mahboubi, University of Nebraska, Medical Center, School of Medicine, Dept. of Epidemiology, *42nd & Dewey Aves., Omaha, Nebraska* 68105 (D-IARC-79-899)

Recent reports from Australia, Canada, Europe and the United States suggest that the incidence of the hitherto rare liver cell tumors in young women has increased. Several case reports of hepatocellular adenomas in young women using oral contraceptive pills prompted an epidemiological investigation to obtain quantitative information concerning the validity of a relationship between hepatocellular adenomas and the use of steroid hormones. Although these tumors are benign, they cause serious or fatal hemorrhage. This investigation seeks to establish their incidence in order to determine the degree of risk associated with oral contraceptive use and, if possible, the type of pill responsible for this increase.

CANCER MORTALITY PATTERNS IN NEBRASKA (1950-1975)

E. Mahboubi, University of Nebraska, Medical Center, School of Medicine, Dept. of Epidemiology, *42nd & Dewey Aves., Omaha, Nebraska* 68105 (D-IARC-79-900)

It has been repeatedly said that 60-90% of all cancer is caused by environmental factors. Alterations in the health patterns of the general population occur as a result of man's ever-changing way of life and introduction of a variety of substances into his environment. Overall, cancer incidence rates have been fluctuating during the past three decades; there has been a steady decline in some cancer types and a substantial increase in others. Information on the geographical distribution of cancer has been particularly useful in developing and testing aetiologic hypotheses. Nebraska, with a population of one and half million, shows significantly higher rates of leukaemia and colon cancer than the national average. Therefore, an age-adjusted analytical study of the cancer mortality patterns by county in the last 25 years (1950-1975) is being undertaken to determine the possible relationships between specific cancer types and associated environmental factors.

AN EPIDEMIOLOGICAL STUDY OF THE LONG-TERM EFFECTS OF GRISEOFULVIN IN MAN

E. Mahboubi, University of Nebraska, Medical Center, School of Medicine, Dept. of Epidemiology, *42nd & Dewey Aves., Omaha, Nebraska* 68105 (D-IARC-79-901)

This study examines epidemiologically the anti-fungal drug griseofulvin. The study has been initiated as a result of recent findings by the Eppley Cancer Institute indicating that griseofulvin induces thryoid tumors in rats. The drug had previously been found to induce liver neoplasms in mice. Based upon available information the objectives are: (1) To identify, locate and establish groups of persons throughout the United States, and possibly some Western European countries who have, in the past 18 years or so, used griseofulvin for treatment of various skin diseases and other illnesses, and (2) to evaluate the possible carcinogenicity and teratogenicity of the drug.

CASE-CONTROL STUDY OF WATER QUALITY AND CARCINOGENESIS IN PENNSYLVANIA

A. Bahn, University of Pennsylvania, School of Medicine, Dept. of Community Medicine, *36th & Hamilton Walk, Philadelphia, Pennsylvania* 19174 (D-IARC-79-1018)

This is a case-control retrospective study of colon cancer in four counties - Philadelphia, Delaware, Chester, and Bucks - of Pennsylvania. Decedent cases (colon cancer) and controls (deaths due to causes other than cancer) will be drawn from the state mortality records and the next-of-kin listed on the death certificates will be interviewed. Live cases will be selected from hospital records and controls will be randomly selected from the counties. For each case and control information will be obtained concerning residence, occupation, and medical histories, smoking habits, dietary patterns and medicine usage. Detailed chacterization of water sources, treatment methods and chemicals will be obtained. Relationship(s) between routine water analyses and the detailed organic analyses will be investigated for use in historical extrapolation of specific organic contaminant levels in the water. A further major goal of the project is to investigate and compare alternative case-control study methods. Effectiveness of using next-of-kin of decedents for determining relevant exposure will be compared with the use of live cases. Effect of time between death and interview in reliability and usefulness of data will be evaluated. The methodological information obtained will be useful in future investigations of the role of water constituents in the development of chronic diseases.

EPIDEMIOLOGY OF GASTRIC CANCER AND PRECURSOR LESIONS

P. Correa, Louisiana State University, Medical Center, School of Medicine, Dept. of Pathology, *1542 Tulane Ave., New Orleans, Louisiana* 70112 (D-IARC-79-819)

The possible relation between nitrites in the environment and gastric carcinogenesis is being investigated. Nitrites and nitroso compounds are being estimated in the gastric juice and in local foods of the population of Narino, Colombia, where a high prevalence of gastric cancer and precursor lesions has been found. The role of chronic atrophic gastritis in carcinogenesis is being investigated in prospective studies of the population.

STUDIES OF CANCER EPIDEMIOLOGY IN LOUISIANA

P. Correa, Louisiana State University, Medical Center, School of Medicine, Dept. of Pathology, *1542 Tulane Ave., New Orleans, Louisiana* 70112 (D-IARC-79-820)

Based on the frequency of different types of cancer in the State of Louisiana as recorded by mortality statistics and the Louisiana Tumor Registry, studies of analytical epidemiology and geographical pathology are planned and conducted. The main emphasis for 1978-79 is on respiratory cancer since high rates in the southern parts of the State contrast with relatively lower rates in the north. A survey of smoking patterns and a case-control study are being conducted. The aim of the study is to gain some information as to what proportion of the excessive risk can be explained by excessive smoking, occupation and environmental pollution. Five southern Louisiana parishes (counties) have been chosen to be compared with five northern parishes. The lung cancer death rate in the southern parishes is twice that of the northern parishes. A systematic sample of adult males in the 10 parishes has been chosen and will receive mail questionnaires. Lung cancer patients in the hospitals serving the residents of the 10 parishes will be interviewed. A hospital non-cancer control matched by age, sex and race will also be interviewed. In addition, a similarly matched healthy control from the same general neighborhood will be interviewed.

2.1792,

WATER SOURCES AND CHARACTERISTICS AND RISK OF MALIGNANCIES OF SELECTED SITES IN SELECTED LOUISIANA PARISHES

M.S. Gottlieb, Tulane University of Louisiana, School of Medicine, Dept. of Medicine, *1430 Tulane Ave., New Orleans, Louisiana* 70112 (D-IARC-79-822)

In order to determine whether certain drinking water sources predispose individuals to cancer, deaths from cancer of selected sites will be matched to control deaths from non-cancer (non-related causes) within groups of selected parishes with similar characteristics except having differing water sources (river and ground). Matching will be for age, sex, race, and year of death. Cases and controls will be characterized by place of birth, ancestry (Acadian or otherwise), water source and characteristics, occupation and industry, and distance from industry. Length of time on water source for individuals will be determined from residence data, characteristics of the water during the last ten years of life, as well as distance of the residence from local industries characterized by type, size and length of exposure time. These factors will be compared for cancer deaths and non-cancer deaths to determine the contribution of single and multiple variables to the likelihood of dying from cancer. An incidence study will follow for selected sites and parishes where the mortality risk is high. This will be followed by a case/control interview study, including carcinogen screening for selected parishes at high risk for selected sites.

EFFECT OF EARLY DETECTION AND TREATMENT ON SURVIVAL FROM LUNG CANCER

M.R. Melamed, Memorial Sloan Kettering Cancer Center, Dept. of Pathology, *1275 York Ave., New York, New York* 10021

This study was undertaken to determine whether systematic, periodic examinations of sputum cytology, supplementing chest x-ray, could lead to earlier detection of lung cancer in a high risk group and to a reduction in death rate. The population chosen for study is volunteer men, in the New York metropolitan area, over the age of 45 years, who smoke more than one pack of cigarettes daily. A total of 11,000 men will be recruited into the study and all will have

posteroanterior and lateral chest x-rays annually; approximately half will also have sputum cytology examinations at four-month intervals. The study is expected to require 5-10 years, and is being conducted in cooperation with the Mayo Clinic Foundation and Johns Hopkins University where additional populations are being surveyed in the same fashion.

EPIDEMIOLOGY OF MINIMAL BREAST CANCER IN INITIALLY ASYMPTOMATIC WOMEN

B.S. Pasternack, New York University, School of Medicine, Dept. of Environmental Medicine, *550 1st Ave., New York, New York* 10016 (D-IARC-79-943)

The goal of this study is to determine, by means of risk factor analysis, whether minimal breast cancer in initially asymptomatic women is essentially different from clinical breast cancer or whether it is an early manifestation of the same disease. Demographic and medical data recorded at the Guttman Breast Diagnostic Institute, which has been offering free breast examinations to women living in New York City since 1968, will be utilized. The study group will consist of an estimated 880 cases detected up to the end of 1978 and a random selection of approximately 2,700 controls. Two independent histopathological diagnoses will be obtained. Cases will be compared according to three tumor criteria: degree of invasiveness, aggressiveness (the ratio of prevalent to incident cases), and histological type. Controls will be used to confirm relative risk estimates for study factors. Comparison of all cases to controls should result in estimates of relative risk within the range found at other screening centers, whereas the comparisan of clinical cases to controls should provide estimates within the same order of magnitude as registry data.

MORTALITY STUDY OF OCCUPATIONAL EXPOSURE TO HALO ETHERS

B.S. Pasternack, New York University, School of Medicine, Dept. of Environmental Medicine, *550 1st Ave., New York, New York* 10016

Chloromethyl-methyl ether (CMME) and his-chloromethyl ether, an impurity (2-8%) in commercial CMME, are alkylating agents having diverse use in the chemical industry. Animal studies have demonstrated that both compounds are potent lung carcinogens. A retrospective cohort study of occupational exposure to CMME was initiated in 1972 to evaluate the human carcinogenicity of these compounds. The initial survey showed a clear excess of respiratory cancer among the CMME-exposed workers, and a strong exposure-response relationship. Other findings among the exposed workers were a considerable number of respiratory cancers at early ages (before age 45), an excess among both smokers and non-smokers, and an inverse relationship between dose and respiratory cancer latency. Particularly because of the latter finding, another mortality survey is underway to better characterize the risk for those with lower exposure levels. The survey will include all seven major CMME producer and user firms in the USA for the time period 1948-1979. An estimated 2,000 CMME-exposed workers and 3,500 unexposed workers will be available for study.

A STUDY OF CANCER FOLLOWING MULTIPLE FLUOROSCOPIES

A.B. Miller, University of Toronto, *92 College St., Toronto, Ontario, Canada* M5S 1B2

This cohort study is designed to evaluate the carcinogenic risk from ionizing radiation in the dose range 0 to 100 rad and for the major cancer sites to establish if there is a possible dose-response relationship. The study population consists of patients first admitted to Canadian tuberculosis sanitaria between the years 1930 and 1952. A substantial proportion (40 to 50%) were fluoroscoped regularly in conjunction with artificial pneumothorax treatment and consequently accumulated a substantial radiation dose consisting of many exposures over a period of time. Information on the admission and treatment records of these patients has been extracted from the original sanitaria files. The data, consisting of approximately 130,000 records, have been keypunched. Two computerized record linkage steps using the identifying information present on the records are currently being undertaken. The first is to internally link the records so that admissions referring to the same individual will be brought together to form a composite record. The second step is to link these composite records to the mortality data base maintained by Statistics Canada for the years 1950 through 1974, in order to ascertain the mortality experience of the cohort. A dosimetry study has been completed and published (Health Physics 35(2):259-70, 1978) which determines the dose experienced by various body organs exposed to radiation from fluoroscopies. The dosimetry information will be applied to the individual patient records in order to estimate the radiation dose received by each patient. The analysis will consist of estimation of relative risks with respect to mortality for different cancer sites as a function of dose calculated relative to those members of the study population who are not fluoroscoped.

EFFICIENCY OF CLUSTER ANALYSIS TECHNIQUES

R. Chen, Israel Inst. for Biological Research, Dept. of Epidemiology, *P.O. Box 19, Ness Ziona, Israel* (D-IARC-78-290)

The fact that very little (if any) clarification of the aetiology of rare diseases in general and of Hodgkin's disease in particular can be attributed to studies in which cluster analysis techniques were employed, stresses the need for evaluation of the efficiency of these techniques. A few studies have dealt with this topic in the past, mostly by applying one or more of these techniques to real (but reduced in size) data sets composed of cases with known infectious disease (such as poliomyelitis). The present study deals with the efficiency of three cluster analysis techniques (Knox's, Emm's and Mantel's) by applying each of them to simulated data sets. So far, the simulation of these sets were made according to each of two epidemiological models which were adapted to resemble in number of cases the data of Hodgkin's disease in Israel. This part of the study was carried out by the investigator in the National Institutes of Health, National Cancer Institute, USA. A continuation of this study is being carried on now in the Dept. of Epidemiology in the Israel Institute for Biological Research. The aim is to formulate a number of possible epidemiological models, based as much as possible on hints stemming from previous studies; to simulate replicate sets according to each of the models; then to apply cluster analysis techniques to those sets. The results will indicate the chances of revealing clustering among Hodgkin's disease cases as well as the preferable technique among those applied.

TIME TRENDS IN MORTALITY RATES

T. Hirohata, Kurume University, Dept. of Public Health, *67 Asahi-Machi, Kurume City 830, Fukuoka, Japan* (D-IARC-79-354)

Mortality rates specific for race (Caucasian, Japanese, Chinese, Hawaiian and Filipino) sex, five or ten year age groups and 80 selected causes of death have been computed for each decennial census year in Hawaii, from 1910 to 1970. Computed mortality rates actually represent average annual mortality rates for the 5-year peri-censual periods. Because of changes in ICD code numbers over these years, every death was recoded by computer or by hand, using a common coding scheme. These data are being analysed for secular trends in Hawaii and for comparison with corresponding trends in Japan and on the US mainland.

SPATIAL AND TEMPORAL VARIATIONS IN FOUR COMMON CANCERS IN BLACK GOLD MINERS FROM SOUTHERN AFRICA

J.S. Harington, National Cancer Assn. of South Africa, Cancer Research Unit, *9 Jubilee Rd., Johannesburg 2000, Transvaal, South Africa* (D-IARC-79-483)

In previous work on the gold miners, the pattern of cancer in Black gold miners over the eight-year period 1964-71, comprising 2,926,461 man-years of employment, was studied. Of the 1,344 cancers found, primary liver cancer accounted for 52.8%, oesophageal cancer 12.1%, cancer of the respiratory system 5.4%, and cancer of the bladder 4.8%. Analysis of the spatial distribution of these four cancers, both on subcontinental and local scale, showed distinct gradients of significantly higher and lower incidence than expected. In the case of primary liver cancer in Mozambique and oesophageal cancer in Transkei, the spatial distribution reflects closely that found in the general resident population of each territory. The crude incidence rate of primary liver cancer in gold miners from Mozambique dropped sharply over the period of the survey. The survey continues.

YORKSHIRE BREAST CANCER PROJECT

R.A. Cartwright, Yorkshire Regional Cancer Org., Dept. of Epidemiology, *Leeds LS16 6QB, England, United Kingdom*

All new cases of breast cancer presenting to a group of surgeons in Yorkshire, are being investigated. A series of predictive variable and detailed descriptions in clinical, surgical and pathological terms are now being analyzed. In the first instance the analyses will concern factors which might lead to the first relapse of each case. The study has accumulated over 700 cases to date and will realize over 1000 before the end of the collection phase.

The object of the study, besides its predictive and descriptive valve is to study the epidemiology of breast cancer in Yorkshire.

STUDIES ON THE EPIDEMIOLOGY AND ERADICATION OF LYMPHOID LEUKOSIS VIRUS IN CHICKENS

L.N. Payne, Houghton Poultry Research Station, Leukosis Experimental Unit, *Houghton, Huntingdon PE17 2DA, England, United Kingdom*

Lymphoid leukosis virus infection is widespread in commercial poultry populations, and is responsible for economically significant losses from leukosis. One approach to control of losses is by eradication of leukosis virus from commercial breeding stock. A detailed study is in progress on the relationship between the infective status of breeding birds and the transmission of virus to their progeny, with particular reference to ways of detecting dams which do not transmit virus. From information so gained two groups of breeding birds have been produced, one selected for freedom from virus infection and the other - an unselected control group, and comparisons of these groups are in progress.

SOME MORBIDITY DATA ON MAMMARY CANCER AND ITS NEGLECT

A. Papolczy, Inst. for Postgraduate Medical Education, Surgery Clinic, *Szabolcs 35, 1387 Budapest 112, Hungary*

In the evaluation of the follow-up data on 1155 female mammary cancer patients according to region, a correlation between the rate of urbanization and cancer neglect could be observed. Regarding profession, industrial workers consulted doctors in the earliest stage of their disease. Patients of a higher educational level showed relatively lower rates of neglect. The first complaint was, in 80% of all cases, the palpable nodule. Fifteen percent of patients from all types of regions consulted doctors at one year's delay and a decrease in the rate of neglect can be attributed to frequent population scanning, self detection, and increased health education.

REPRODUCTIVE OUTCOMES ASSOCIATED WITH PATERNAL EXPOSURE TO VINYL CHLORIDE MONOMER

P.A. Buffler, University of Texas, Medical Branch at Galveston, School of Medicine, Dept. of Preventive Medicine & Community Health, *300 University Blvd., Galveston, Texas* 77550

The carcinogenic potential of vinyl chloride has been characterized and, recently, vinyl chloride has been described as a mutagen and a teratogen. Recognized fetal wastage has been established as an indicator of mutagenic effects due to environmental or occupational exposures. A cohort of 249 men who had known exposure to vinyl chloride monomer (VCM) and who were currently married was identified from the work force of a major chemical company. A comparison group of non-exposed male employees with similar socioeconomic characteristics was also identified. An interview methodology was developed to obtain complete reproductive histories from the wives of the employees. Data for each pregnancy outcome will be correlated with the husband's work history. Only those pregnancies which occurred while the husband was exposed to VCM or within the subsequent three months will be considered 'at risk'. Data regarding other factors associated with pregnancy outcomes have also been collected.

Analysis is near completion and has focused on fetal death, congenital defects, fertility rates and infant mortality.

IODINE METABOLISM AND BREAST CANCER

B.A. Eskin, Medical College of Pennsylvania, School of Medicine, Dept. of Obstetrics & Gynecology, *3300 Henry Ave., Philadelphia, Pennsylvania* 19129

Research from this laboratory and others has indicated that glandular atypia occurs in the breast tissue of rodents under conditions of iodine deprivation. The cellular changes caused by iodine deficiency are intensified by aging. Additionally, some evidence shows further modifications of breast histology in iodine deficiency by steroid hormones such as estrogen and testosterone and pituitary hormones such as gonadotropins and thyrotropins.

There has been controversy concerning the effect of iodine deficiency on stimulation and maintenance of cancer of the breast in rodents when carcinogens are employed. However, neither within this induced neoplastic framework nor with the dysplastic changes caused by deficiency alone, have laboratory studies of the pathway of intracellular iodine been possible.

The main objective of our basic work is to study intracellular iodine metabolism in breast tissue. The techniques to be employed have been used in our laboratories with success and are described in our recent publications. The metabolic events will be compared with the histopathology obtained from the same experimental animal. By this protocol, we project results which may provide an insight into the mechanism whereby iodine influences breast growth and development and explain why, in its absence, abnormal responses may occur.

In light of the diverse iodine deficiency in the U.S. and other countries, this epidemiological factor will be researched by basic technics and then further extended to clinical areas.

A RETROSPECTIVE STUDY OF CANCER OCCURRENCE

M.A. Rahim, Bangladesh Cancer Epidemiology Research Program, Radiotherapy Centers in Bangladesh, *49 E. Azimpur Gov. Estate, Dacca 5, Bangladesh* (D-IARC-79-46)

The relative frequency of cancer will be determined by analyzing the record of patients admitted to hospital and treated in different radiotherapy centers since 1964. This study will be conducted under the auspices of the Bangladesh Cancer Epidemiology Research Program.

BANGLADESH CANCER EPIDEMIOLOGY RESEARCH PROGRAM

M.A. Rahim, Bangladesh Cancer Epidemiology Research Program, Radiotherapy Centers in Bangladesh, *49 E. Azimpur Gov. Estate, Dacca 5, Bangladesh* (D-IARC-79-47)

OBJECTIVE: To examine the relative frequency of all cancers at hospitals with radiotherapy facilities available which have been selected to participate in the study. Participation of other hospitals without a radiotherapy center is voluntary. Consultants attached to participating hospitals are coinvestigators. After interview and examination a clinical report is prepared, one for each patient, in the ad hoc tumor registry of BCERP. The records are sent to a central location for compilation and statistical analysis. Three articles have been published and results show that cancers of the larynx, lung and oropharynx are frequent in males, and cancers of the cervix, breast and oral cavity in females.

HISTORICAL REVIEW OF MALIGNANT MELANOMA IN ALBERTA 1967-1976

J. Birdsell, Calgary Cancer Clinic, Dept. of Biostatistics, *2104 2nd St. S.W., Calgary, Alberta, Canada* T2S 1S5 (D-IARC-79-59)

Records of all patients diagnosed as having melanoma of skin or eye during the past ten years were indentified from the Alberta Cancer Registry. These files were reviewed and information was collected on sex, age, residence history, method of diagnosis, site, pathological features, stage at diagnosis, duration of stages, sites of metastases, treatment and survival. Analysis of data will provide information on the incidence of melanoma, treatment given, recurrence and survival rates and the correlation of various factors with prognosis.

EPIDEMIOLOGICAL ASPECTS OF CARCINOMA OF THE CERVIX

C. Giordano, Faculdade de Ciencias Medicas da Santa Casa de Sao Paulo, Dtpo. de Obstetricia e Ginecologia, *Rua Dr. Cesario Mota Junior, N 112, Sao Paulo 01221, Brazil* (D-IARC-79-53)

The low income female population constitutes the major portion of those attending the clinics of general hospitals in Brazil for screening for cancer of the uterine cervix. This study aims to characterize, in this low revenue population, those that are at 'high risk' for cervical cancer utilizing 18 variables obtained from complete gynecological examination, cervical cytology, colposcopy and biopsy. The preliminary work of collection of the data has been undertaken over the past two years. The data will now be processed by discriminate analysis to determine which of the variables examined could be a contributing factor to cervical cancer.

EPIDEMIOLIGY OF CANCER IN THE NATIVE INDIAN POPULATION OF ALBERTA

L.M. Laing, University of Alberta, Dept. of Community Medicine, *Edmonton, Alberta, Canada* T6G 2E1 (D-IARC-79-69)

Native Indian populations are in cultural transition. The movement away from aboriginal patterns of adaptation is accompanied by changes in lifestyle and exposure to factors which may increase the risk of cancer. Risk factors include changes in reproductive patterns, a diet based on processed foods, occupational exposure to toxic substances, and increasing use of alcohol, tobacco, and drugs. Published information on cancer incidence and morality among native populations is relatively scant. The pattern of incidence of cancers among native Indian and Eskimo popualtions is different from that among other residents of North America. Malignant disease may once have been rare in native Indian and Eskimo populations. Cancers of the gallbladder and nasopharynx are significantly more frequent among native Indians. Cancers of the cervix and lung appear to have increased in relative prevalence. The Government of Canada maintains records of registered Indians through the Departments of Indian and Northern Affairs and Health and Welfare. There are approximately 32,000 registered Indians who are residents of Alberta. Lists of registered Indians will be matched with files of the Alberta Cancer Registry and with death certificates. An historical prospective study of cancer incidence and mortality among native Indians will be undertaken. It is estimated that for the study period 1974-78 there will be about 100 cancer deaths.

OCCUPATIONAL MALIGNANCIES AMONG PETROCHEMICAL WORKERS OF ALBERTA

M.G. Grace, Dr. W.W. Cross Cancer Inst., Dept. of Biostatistics, *11560 University Ave., Edmonton, Alberta, Canada* T6G 1Z2 (D-IARC-79-68)

A study is in progress to demonstrate possible relationships between occupational exposure to toxic substances and cancer incidence, mortality and mortality from all causes in Alberta. Retrospective data are being collected on approximately 4,500 workers occupationally exposed to chemicals, and unexposed control group similar in size and other characteristics. Sources of data are: a self-administered questionnarie, Vital Statistics, the Provincial Cancer Registry and Patient Index system.

TRENDS IN CANCER INCIDENCE

M.G. Grace, Dr. W.W. Cross Cancer Inst., Dept. of Biostatistics, *11560 University Ave., Edmonton, Alberta, Canada* T6G 1Z2 (D-IARC-79-67)

This study will examine the temporal variation in cancer incidence in Alberta over the years 1961-1977, and fit simple regression models to determine significant increasing or decreasing trends. All sites will be analyzed involving the processing of about 68,000 malignancies. These form the basis of comparisons with similar studies, and will be useful for the monitoring of preventive measures, occupational studies and as a long-range planning tool.

CHILDHOOD CANCER IN ALBERTA

M.G. Grace, Dr. W.W. Cross Cancer Inst., Dept. of Biostatistics, *11560 University Ave., Edmonton, Alberta, Canada* T6G 1Z2 (D-IARC-79-64)

Files on children diagnosed with cancer and registered with the Alberta Cancer Registry during the past 10 years are being reviewed. In addition to descriptive statistics on incidence and mortality by age, sex, site, and histology, this study will provide

information on survival rates. Variables which might provide leads to aetiological factors include occupation of father, place of birth and/or residence, reproductive history of mother, presence of congenital malformations, and family history of cancer. The total number of childhood cancer cases diagnosed in Alberta has increased from 71 cases in 1970 to 110 cases in 1977 (0-19 years of age). The incidence of childhood cancer in Alberta will be compared with that of other population-based registries in Manitoba, Saskatchewan, Norway, and Finland, and with results of the U.S. Third National Cancer Survey. The first stage of this study will consist of an analysis of data from review of files for the three-year diagnosis period, 1975-77, in order to assess the quality of information available for certain variables and refine the review protocol. Missing information will be sought from vital statitics registrations in the province.

INCIDENCE OF CANCERS OF THE STOMACH AND OESOPHAGUS IN ALBERTA, 1969-73

K. Morgan, University of Alberta, Dept. of Genetics, *Edmonton, Alberta, Canada* T6G 2E1 (D-IARC-79-71)

The geographic distribution of cancers of the stomach and oesophagus in Alberta, diagnosed during the period 1969-73, will be studied in an attempt to define high-risk subpopulations among residents of the province. Approximately 900 cases have been verified by review of patients' files for sex, pathology, year of diagnosis, and residence at time of diagnosis. Additional study variables include birth date, birth place, ethnic origin, and major occupation. The other primary source of information for these variables is death certificates registered in the Province of Alberta. Some preliminary results of mapping age-adjusted incidence of cancers for both sites and sexes combined, by residence at time of diagnosis, include identification of cluster of three counties with statistically significantly increased standardized incidence ratios and a major city with a statistically significantly decreased standardized incidence ratio. These analyses will be refined, and associations with birth place, length of residence, occupation, and ethnicity (implicating life style factors) will be sought.

GYNECOLOGICAL CYTOLOGY REGISTRY, NOVA SCOTIA

G. Anderson, Victoria General Hospital, *5788 University Ave., Halifax, Nova Scotia, Canada* B3H 2Y9 (D-IARC-79-72)

A computerized gynecological cytology registry has been designed for the Province of Nova Scotia. The objectives of the registry are as follows: (1) To provide complete and accurate information regarding the numbers and location of women being screened and the number of Papanicolaou smears being examined annually throughout the Province of Nova Scotia; (2) to provide information for use in the establishment of a province-wide quality control program in the area of gynecological follow-up of cases who have abnormal cytology; (4) to provide epidemiological data related to malignant and pre-malignant disease of the uterus in the Province of Nova Scotia. Data are being collected from all laboratories providing a gynecological cytology service in the Province of Nova Scotia using standardized diagnostic terminology and standardized requisition report form. The design of the computer program will provide annual and semi-annual reports relating to the numbers of women being screened in the province by age and county distribution. Information regarding abnormal smears and subsequent colposcopy and biopsy findings are also incorporated in the routine computer printout. Since Nova Scotia has a relatively small and stable population of approximately 300,000 women at-risk of developing cervical neoplasia, it is hoped that the program will provide useful information in relation to the distribution and epidemiology of this disease in this population.

CARCINOMA IN-SITU AND DYSPLASIA OF UTERINE CERVIX IN RELATION TO AGE, PARITY AND BEGINNING OF SEXUUAL RELATIONS

C.A. Masi, Inst. Nacional Regional de Oncologia, Gynaecology Section, *Bv. Zavalia 3399, C.C. No. 366, 3000 Santa Fe, Argentina* (D-IARC-79-5)

The aim is to determine the age at which carcinoma in situ and dysplasia occur for comparison with findings of authors elsewhere, using a sample group consisting of all 'healthy' patients seen at the Department of Gynecology. Data concerning the age at disease onset will be taken from the Registry. At the beginning of this study only age was considered; in the last months, parity and beginning of sexual relations have been added.

A MORTALITY STUDY OF NICKEL WORKERS IN ONTARIO

R.S. Roberts, McMaster University, Dept. of Clinical Epidemiology & Biostatistics, *1200 Main St. W., Hamilton, Ontario, Canada* L8S 4L8

This study ultilizes a fairly conventional historical prospective design to compare mortality patterns in nickel workers over a 27 year follow-up period. The study cohort consists of approximately 70,000 men working at Sudbury and Port Colborne. Eligible subjects are males with six months or more of accumulated service who worked for the company (or who were receiving a pension) on or after 1 January 1950. The mortality experience of these men through to the end of 1976 will be ascertained from the Statistics Canada registry of death certificates using a record linkage procedure based on full name, date of birth and 'last known alive' date. A series of tactics are being undertaken to estimate the accuracy of the matching. The analysis of this data will relate features of the detailed occupational histories of these men to cause-specific mortality. Of particular interest are the relationships of cumulative nickel sulphide and nickel oxide to respiratory cancer, but other cancers and contaminants will also be considered. In addition, exposure in terms of years of duration in particular occupations (i.e., the sinter plant) will be analyzed.

A STUDY OF MALIGNANCY AND OTHER ASBESTOS-RELATED DISEASES IN RELATION TO CROCIDOLITE MINING AND ENVIRONMENTAL EXPOSURE AT WITTENOOM GORGE

M.S. Hobbs, University of Western Australia, Unit of Clinical Epidemiology, *Nedlands, W. Australia 6009, Australia*

The aim of the study is to determine the incidence of mesothelioma, bronchogenic carcinoma and other malignant tumors in workers previously employed in mining and milling crocidolite at Wittenoom Gorge, Western Australia, between 1942 and 1966, in relation to duration of exposure and smoking habits. The risk of mesothelioma in the relatives of workers and other Wittenoom Gorge residents not directly involved in mining crocidolite will also be assessed. Work is continuing to determine the vital status and present whereabouts of approximately 6,500 men formerly employed at Wittenoom Gorge through electoral rolls, other population registers and cancer and death registers in different Australian States. Commencing in 1979 a questionnaire will be sent to all former Wittenoom Gorge workers so far located to obtain further details concerning occupation and smoking habits. Respondents will be followed for as long as necessary to determine the interaction between crocidolite exposure and smoking in relation to the development of bronchogenic carcinoma. This questionnaire will also seek information concerning relatives of former asbestos workers also living at Wittenoom Gorge. This will be supplemented, if possible, by information from local government and school records to establish a roll of persons not directly involved in processing crocidolite but possibly at risk of developing mesothelioma from environmental exposure. Procedures will be established to monitor this cohort for the future development of mesothelioma.

INCIDENCE OF TESTICULAR TUMORS WITH EMPHASIS ON POSSIBLE RURAL PREPONDERANCE AND OCCUPATION

T.F. Sandeman, Peter MacCallum Hospital, Urological Service, *278 William St., Melbourne, Victoria 3000, Australia* (D-IARC-79-21)

Previous surveys of the testicular tumor population presenting to the Peter MacCallum Clinic have suggested an increased incidence in patients from rural areas. Articles published since then have confirmed this trend overseas. Futhermore, evidence in the literature indicates occupational risks for a large number of cancers. Two studies are being carried out: (1) A survey of all testicular neoplasms in the State of Victoria from 1950 to 1978, using records from pathology laboratories, to determine any increase in incidence and possible rural preponderance. (2) A case-control study of cases at Peter MacCallum since 1952, investigating residence (metropolitan, town or rural), occupation, place of birth, religion and possible exposure to carcinogens. All cases have been histologically classified to reveal relationships according to classification. Retrospective studies covering all the available case material are being carried out (a) to increase the numbers and (b) to detect any change in trends, and a survey of pathologists' records is being conducted.

ANALYSIS OF COMPUTERIZED DATA ON MALIGNANT MELANOMA

H.M. Shaw, University of Sydney, Dept. of Surgery, *Sydney, N.S.W. 2006, Australia* (D-IARC-79-35)

A detailed study of malignant melanoma is being made from two points of view: factors in the host and tumor that influence the behavior of the tumor, i.e., disease-free periods and site and type of metastases when they develop. The factors being investigated from the existing records include: (1) Identification of high risk individuals. (2) Role of sunlight exposure. Studies from the United States and Europe indicate an inverse relation between incidence of melanoma and geographic latitude. However, there appears to be little correlation between morbidity and mortality. Because morbidity has increased more than mortality, there is a need to establish whether: (a) the increase in incidence is indeed a real effect or an artifactual one, resulting from earlier diagnosis and the more frequent removal of superficial tumors, and (b) melanomas induced by sun exposure have a lower degree of malignancy than those always covered by clothing. (3) Tumor factors possibly unrelated to sunlight exposure. Morbidity may have increased more than mortality due to changes in the biological nature of the tumor, such as histological type, grade of mitotic activity, level of invasion or tumor thickness. (4) Patterns of dissemi-

nation of melanoma. It is important to determine why melanoma spreads by either rapid hematogenous transmission, by slower direct lymphatic extension or by extension through successive echelons of local and regional lymphatics.

DIET, ALCOHOL, AND HORMONAL STATUS IN COLORECTAL CANCER

J.D. Potter, Commonwealth Scientific & Industrial Research Org., Div. of Human Nutrition, *Kintore Ave., Adelaide, S. Australia 5000, Australia*

Consumption of alcohol in Australia varies considerably between ethnic and social groups. Diet is presumed to be more homogeneous, which makes it less amenable to analytical study than alcohol. However, some critical dietary items may vary considerably within the population. It has been demostrated that the ratio of male:female incidence rate of colon cancer is about 1, whereas that for rectal cancer is around 2. Further it has been shown that nulliparity is a risk factor for colon cancer in a way similar to that for breast cancer. A case-control study investigating the relationship of both colon and rectal cancer separately, (paying particular attention to anatomical location) with dietary fat, dietary fiber, vitamins A and C and parity and hormonal status is now being undertaken. Cases are identified using a community-based cancer registry, while controls are drawn from the general community. Approximately 400 cases and 800 controls will be studied.

CENTRAL CANCER REGISTRY

N.J. Gray, Anti Cancer Council of Victoria, Central Cancer Registry, *90 Jolimont St., East Melbourne, Victoria 3002, Australia* (D-IARC-79-17)

The Central Cancer Registry continually monitors hospital data from large hospitals in Victoria, covering an estimated 50% of cancers occurring. Clinical data are recorded by medically qualified registry personnel and follow-up to provide survival data is rigorous. The registry yields information on relative frequency as well as treatment trends and results, and is available as a case-identifying centre for retrospective epidemiological studies. A population-based registry is now being developed to register all cases of cancer within the State of Victoria to enable incidence and prevalence to be established. Registry data are made available to research workers on request and advice on statistical and epidemiological techniques is also given.

2.1843,

MONITORING THE OCCUPATIONAL ENVIRONMENT FOR CARCINOGENS - A PILOT STUDY IN MONTREAL

J. Siemiatycki, Armand Frappier Institut, Centre de Recherche en Epidemiologie et Medecine Preventive, *531 Blvd. des Prairies, Case Postale 100, Laval des Rapides, Quebec, Canada* H7N 4Z3 (D-IARC-79-78)

Of the thousands of chemicals in the occupational environment, only a score have at present been demonstrated to be human carcinogens. There is no human evidence one way or another for almost all of the others. The very large number of agents renders inadequate conventional 'one-factor-at-a-time' epidemiologic study methods (case-control or cohort). The objective is to establish an ongoing monitoring system capable of scanning the occupational environment to detect hitherto unsuspected human carcinogens. A case-control type methodology will be used. Cases will be adult male cancer patients hospitalized in the Montreal region. Several sites will be included and each will be analyzed separately. In the pilot study, controls for each site will be selected from among the cases with cancer of other sites. For each man a lifetime history of exposure to a large number of agents will be ascertained. An innovative approach will be developed to ascertain occupational exposures which the worker might not be able to report or recall. This will be based on a self-administered questionnaire followed by an in-depth interview and a matrix relating specific chemical exposures to specific jobs. The matrix will be developed in consultation with experts in the fields of chemical and industrial engineering. A worker's exposure history will be inferred from his job history and the matrix. The analyses will aim to identify high risk chemicals and workplaces. A two-year feasibility study will evaluate diverse aspects such as case ascertainment, data collection methods, and the statistical sensitivity of the system before a long-term system is established.

OCCUPATIONAL AND NON-OCCUPATIONAL RISK FACTORS OF SQUAMOUS CELL CARCINOMA OF SKIN IN THE MONTREAL REGION

F. Aubry, McGill University, Dept. of Epidemiology & Health, *3655 Drummond St., Montreal, Quebec, Canada* H3G 1Y6 (D-IARC-79-83)

Data from the Cancer Registry of the Province of Quebec indicate that skin cancer is one of the leading types of cancer in the Montreal region. Given that the two major risk factors of squamous cell carcinoma of the skin recognized in the medical literature are sunlight exposure and the Celtic characteristics of people and that these factors are not particularly marked in the Montreal region, the possibility exists that other risk factors, particularly occupational, could play role. The objective of this case-control study is to assess the relative risk associated with occupational and non-occupational known and suspected risk factors of squamous cell carcinoma of the skin diagnosed in the Montreal region, specifically occupational exposure to sunlight and/or to chemical agents and radiations. The cases are defined as all cases of squamous cell carcinoma of the skin diagnosed during the two years preceding the beginning of the study in the pathology departments of Montreal hospitals. Two controls matched for sex and age with each case will be selected from among pathology records at the same hospital at which the case was found. The controls will be subjects in whom a pathological diagnosis will have been made for skin condition which is non-malignant and which is not known to be related to the risk factors of squamous cell carcinoma of the skin. Cases of pemphigus vulgaris, bullous pemphigus, intradermal naevus and lichen planus will thus be included. The total number of cases in this study is estimated between 400 and 800. A postal questionnaire on occupation and exposure to environmental factors will be sent to each case and each control and telephone calls will then be made to complete missing information. Data will be analysed by means of a discriminant analysis.

LUNG CANCER MORTALITY IN ALUMINUM REDUCTION WORKERS

G.W. Gibbs, McGill University, Inst. for Mineral Industry Research, Occupational Health & Safety Unit, *Gault Estate, Mont St. Hilaire, Quebec, Canada* J3G 4S6 (D-IARC-79-82)

The study aims to determine the lung cancer mortality of workers in three aluminum reduction plants for the 4 year period 1 January 1974 to 31 December 1977 and to examine the relationship between lung cancer mortality and lengtn of employment and level of tar exposure. The methods to be applied are identical to those in an earlier study of lung cancer mortality (1950-1973) currently in press. The populations under study consist of 2 cohorts employed at aluminum reduction plants, one of 5,406 workers who were working at plant A on 1 January 1950 and the other of 485 workers who were working at plant B on 1 January 1951. The mortality experience from lung cancer for this population was studied to 31 December 1973. The period of observation will now be extended to 31 December 1977. The pattern of mortality for the 2 periods 1950-1973 and 1974-1977 will be examined to determine any change in the relationships between lung cancer mortality and tar exposure.

2.1848,

MORTALITY FROM SPECIFIC CAUSES OTHER THAN LUNG CANCER IN ALUMINUM PLANT WORKERS

G.W. Gibbs, McGill University, Inst. for Mineral Industry Research, Occupational Health & Safety Unit, *Gault Estate, Mont St. Hilaire, Quebec, Canada* J3G 4S6 (D-IARC-79-81)

The aim of the study is to describe the mortality from specific causes other than lung cancer in two cohorts of workers employed in the aluminum reduction industry. The same populations which have been examined for study of lung cancer mortality will be used. The cohorts consist of 5,406 men working at plant A on 1 January 1950 and 485 men working at plant B on 1 January 1951. These workers were traced to 31 December 1973. The analyses will examine (1) whether there is any excess of mortality from specific causes in this industry when compared to expected numbers of deaths based on Quebec rates; (2) the relationship between mortality from specific causes and years of exposure, years since first exposure and tar exposure.

BLADDER CANCER IN THE CENSUS DIVISION OF CHICOUTIMI, QUEBEC

G.P. Theriault, Universite Laval, School of Medicine & Dentistry, Dept. de Medecine Sociale et Preventive, *Pavillon de l'Ouest, Ste. Foy, Quebec, Canada* G1K 7P4 (D-IARC-79-94)

The objective of this retrospective case-control study is to identify the cause of an increased incidence of bladder cancer in the census division of Chicoutimi. All bladder cancer cases reported to the Quebec Tumour Registry and/or all such cases diagnosed by the Chicoutimi Hospital Pathology Laboratory between 1970 and 1975 (total: 91 cases) are included. Each case is matched with two controls of the same age and sex: 1) the first person admitted to the hospital, for a major reason, at the same time as the patient and 2) the person living as close as possible to the patient in the diagnosis year, traced through the register of voters. The 273 individuals are required to complete questionnaire on the following items: consanguinity, residential history, medical history (bladder and kidney conditions), drug and sugar substitute consumption, occupational history, and tobacco, coffee and alcoholic beverage consumption. Histopathological diagnoses are viewed by a pathologist and coded according to Jewett's classification. The risk from one exposure or the combination of two exposures will be estimated. A multiple regression model will be built.

CANCER MORTALITY AMONG VINYL CHLORIDE WORKERS IN SHAWINIGAN, QUEBEC

G.P. Theriault, Universite Laval, School of Medicine & Dentistry, Dept. de Medecine Sociale et Preventive, *Pavillon de l'Ouest, Ste. Foy, Quebec, Canada* G1K 7P4 (D-IARC-79-93)

This retrospective cohort study aims to determine cancer mortality patterns among workers employed in a vinyl chloride polymerization plant, Shawinigan, Quebec, and establish their relationship with age, duration and level of exposure and alcohol and tobacco consumption. All workers employed during at least 5 years from the operative start of the plant until 31 December 1976 will be included. Their life status at the end of the study period, and the cause of death for the deceased, as well as duration and level of exposure to vinyl chloride and alcohol and tobacco consumption, will be determined. These data will be obtained through a questionnaire applied to the worker, or his family if he is dead. The industry, Population Registry and pathologists will also contribute relevant data. Values so obtained will be compared with those for a cohort of workers in the same firm who were not exposed to vinyl chloride. Cancer death rates will almost be compared to Quebec rates for the same period.

POSSIBLE INFLUENCE OF ENVIRONMENTAL POLLUTION ON CANCER MORTALITY IN A POPULATION LIVING NEAR A VINYL CHLORIDE POLYMERIZATION PLANT

G.P. Theriault, Universite Laval, School of Medicine & Dentistry, Dept. de Medecine Sociale et Preventive, *Pavillon de l'Ouest, Ste. Foy, Quebec, Canada* G1K 7P4 (D-IARC-79-92)

This retrospective case-control study aims to determine whether exposure to a factory environment accounts for higher death rates in the population of Shawinigan, Quebec, where vinyl chloride polymerization plant is located. All men aged 25-64 who died from cancer in Shawinigan between 1965 and 1974 will be examined for occupational history, duration of residence in Shawinigan, place of residence there and alcohol and tobacco consumption; they will then be compared with men of similar age who lived in Shawinigan and died at the same time from another cause.

MORTALITY PATTERNS IN A POPULATION LIVING NEAR A COPPER-REFINING PLANT IN ROUYN-NORANDA, QUEBEC

G.P. Theriault, Universite Laval, School of Medicine & Dentistry, Dept. de Medecine Sociale et Preventive, *Pavillon de l'Ouest, Ste. Foy, Quebec, Canada* G1K 7P4 (D-IARC-79-91)

The objective of the study is to assess the possible health effects of toxic effluents on the population of Rouyn-Noranda by studying their mortality patterns. General and specific death rates in Rouyn-Noranda for the period 1965-74 will be determined and compared with those observed in control towns (Drummondville and Val d'Or) and in Quebec. The emphasis will be put on lung cancer and respiratory disease mortality.

2.1853,

CANCER MORTALITY AND DRINKING WATER QUALITY

D.T. Wigle, Canadian Dept. of National Health & Welfare, Lab. Centre for Disease Control, *Tunneys Pasture, Ottawa, Ontario, Canada* K1A 0L2 (D-IARC-79-88)

Cancer mortality rates by sex and site for 100 municipalities will be correlated with water quality. Water samples have been analyzed to determine concentrations of the following: amphibole abestos, chrysotile asbestos, trihalomethanes, total organic carbon, nitrilotriacetic acid, lead, cadmium, zinc, copper, calcium, magnesium and total hardness. For most municipalities, cancer mortality data are available for at least the past 20 years. Cancer mortality rates will be correlated with the water quality data listed above plus other factors (year of fluoridation, source of water).

IDENTIFICATION OF OCCUPATIONAL RISK FOR COLORECTAL CANCER

J.M. Vobecky, Universite de Sherbrooke, Faculte de Medecine, Dept. des Sciences de la Sante Communautaire/Chirurgie, *Sherbrooke, Quebec, Canada* (D-IARC-79-95)

A cluster of five cases of cancer of the large intestine has been observed. The patients had several features in common, including work in the same department of a textile plant. By examining the frequency of colorectal cancer in the population, on the one hand, and these common features, in particular the same long-term occupational exposure, on the other, the study attempted to determine whether this clustering was only due to chance or to occuptional exposure. Occupational history, familial history of cancer, bowel habits, precureor diseases, and predisposing conditions for all colorectal cancer patients occurring from 1965 to 1976 in the area where the plant is located and in the neighboring areas have been studied. Preliminary results, based on 1,500 colorectal cancer cases, show that colorectal cancer is 10 times more frequent among synthetic textile workers than in the non-exposed population (Gastroenterology, 75, 221, 1978). In order to establish the aetiological nature of this association, a retrospective case-control study with three control groups, related to the factor involved, i.e., occupational exposure to synthetic fiber, has been undertaken. These control groups include patients with cancer other than colorectal cancer, patients with diseases other than cancer, and matched neighborhood controls. This ongoing phase of the work will allow elimination of superfluous factors.

FRENCH MESOTHELIOMA REGISTER

J. Bignon, Centre Hospitalier Intercommunal de Creteil, Service Hospitalier Universitaire de Pneumologie, *40 Ave. de Verdun, 94010 Creteil, France* (D-IARC-79-165)

To date 197 proved cases of mesothelioma (mainly pleural) have been reported for the period 1965-1978, a moderate increase over time being noted. Occupational and para-occupational asbestos exposure was recorded in 77 percent and 3 percent of registered cases respectively. As the number of cases notified to the register is obviously an underestimate, it is intended to evaluate the annual incidence of this tumour by retrospective registration. Relationships with asbestos exposure and with other pollutants will be sought, and case-control studies for a dose-response relationship with asbestos carried out using retrospective inquiries and measurements of fibres in tissue.

ESTABLISHMENT OF A REGISTRY FOR DIGESTIVE TRACT TUMOURS IN THE DEPARTMENT OF CALVADOS

C. Chuberre, Centre Hospitalo Universitaire, Service de Chirurgie Digestive, *Av. de la Cote de Nacre, 14033 Caen, France* (D-IARC-79-163)

This Registry has been established to clarify the frequency of these cancers according to site, age, sex, occupation, alcohol and tobacco consumption; to define high risk population groups for each site; and to provide information on the current status of screening (warning signs, diagnostic means, time lag between first symptom and diagnosis and between diagnosis and death). Data are collected from physicians, gastro-enterologists, surgeons, pathologists in towns, hospitals (university hospitals, cancer centres, private and public hospitals), health insurance bodies and the Department Directorate for Health and Social Welfare. Only cases of digestive cancer which have occurred since 1 January 1978 in patients residing in Calvados are included.

SUPPORTED BY (No Supporting Organization Reported) funds n.a.

2.1857,

CALVADOS CANCER REGISTRY

J.M. Robillard, Centre Regional Francois Baclesse, Service de Statistiques, *Rte. de Lion-sur-Mer, 14018 Caen, France* (D-IARC-79-164)

The registry compares cancer morbidity in the Department of Calvados with that in the French regions of Bas-Rhin and Doubs, in other regions bordering France (Geneva, Lausanne, Neuchatel, Saragossa) and in more distant parts (Warsaw, Connecticut, Cuba, southern England, etc.). Morbidity time trends are estimated and compared with those observed in other registries. The geographical distribution of cancer within Calvados is examined to study possible aetiological factors (e.g. predominance of lung cancer in areas with asbestos industries). The Registry records cancer cases in the Department as accurately as possible and assists with the planning of screening and prevention in Lower Normandy.

PRECANCEROUS CONDITIONS OF THE STOMACH

K.S. Varis, Helsingin Yliopisto, Dept. of Medicine, *Fabianinkatu 33, SF00290 Helsinki, Finland*

Atrophic gastritis is a well known risk factor of gastric cancer and severe atrophic gastritis of the body (SAGB) probably carries the highest risk. In the artophic mucosa tissue metabolism is altered, the intestinal mucosa acquiring absorptive characteristics (absorption of carcinogens). Cell maturation and kinetics

are disturbed leading sometimes to the development of epithelial atypia, and the associated achlorhydria may facilitate the development of carcinogenic nitroso-compounds intragastrically. The determination of serum pepsinogen group I (Radio-immuno-assay-method of Samloff), with a very high sensitivity and specificity, is used as a screening method for SAGB. Serum pepsinogen group I determination will also be carried out in a sample of patients with gastric carcinoma to examine possible correlations between SAGB (low serum pepsinogen group I), and the localization and histological type of gastric carcinoma. 100 subjects without any major gastric pathology, such as polyps, peptic ulcer or gastric cancer, will also be studied as part of an international multicentre study proposed by IARC. Gastric biopsies from antrum and body, and samples of gastric juice and blood are taken for estimation of N-nitroso compounds in people living in low or high risk areas.

BENIGN BREAST DISEASE - NATURAL HISTORY AND RELATIONSHIPS TO BREAST CANCER

D.V. Vakil, University of Toronto, Faculty of Medicine, Dept. of Preventive Medicine & Biostatistics, *92 College St., Toronto, Ontario, Canada* M5S 1A1 (D-IARC-79-106)

This retrospective cohort study is designed to delineate the natural history of benign breast lesions, and to determine the ways in which the benign and malignant conditions relate in the same individuals. A cohort of 1,713 women who were biopsied between 1968 and 1973 at the Toronto Western Hospital for possible breast cancer and were found to have benign breast disease has been assembled. Genetic, epidemiological and pathological information will be obtained on these women. This data will be analyzed to assemble descriptive information about the natural history of the benign breast lesions in all patients and also in the patients stratified by histoiogical type of the lesion, and by the presence of microcalcification in the mammogram. These women will be followed up to the year 1981 (8 to 13 years) to (1) obtain additional information about the postulated risk factors of breast cancer and (2) determine the subsequent development of benign or malignant breast diseases among them.

EPIDEMIOLOGICAL STUDY OF BLADDER CANCER

A.B. Miller, National Cancer Inst. of Canada, Epidemiology Unit, Dept. of Preventive Medicine & Biostatistics, *121 St. Joseph St., Toronto, Ontario, Canada* M5S 2R9 (D-IARC-79-103)

The general hypothesis is that there is an association between bladder cancer and a number of environmental factors, including carcinogens encountered occupationally, smoking, medications and beverage intake with specific interest in coffee, other caffeine-containing beverages and artificial sweeteners. Data is also being obtained on consumption of nitrate-containing foods, and independently acquired data on nitrates in drinking water will be related to the respondent's residential history. The study aims to determine the relative contribution of known or suspected factors to the aetiology of bladder cancer. The basic assumption underlying the study is that beverage intake, occupational history, contact with artificial sweeteners etc., can be determined through the use of a questionnaire. A detailed questionnaire seeks lifetime history of occupation, residences, sources of drinking water, contact with certain occupations and chemicals, etc., beverage intake, use of sugar substitutes and foods containing artificial sweeteners, consumption of meats and meat products containing nitrates, history of illnesses including bladder and kidney infections, history of analgesic consumption, and history of tobacco consumption in all its forms. The study is of a case/control nature and includes all newly diagnosed cases of bladder cancer from April 1, 1974 to June 30, 1976 in two geographically distinct areas of Canada where substantial contribution of occupational factors to the causation of bladder cancer is not suspected, namely British Columbia (BC) and the Atlantic provinces of Nova Scotia and Newfoundland. Neighborhood controls were utilized, being matched to the cases by sex, age and area of residence on a one to one basis. The questionnaire was administered to both cases and controls in their own homes by specially trained interviewers. Four hundred and one case/control pairs in BC and 231 in the Atlantic Provinces are available for analysis. Part of this work has now been published.

NATURAL HISTORY OF DYSPLASIA OF THE UTERINE CERVIX

A.B. Miller, University of Toronto, *92 College St., Toronto, Ontario, Canada* M5S 1B2 (D-IARC-79-105)

In most models of the natural history of squamous carcinoma of the cervix, dysplasia is regarded as the first recognizable pathological process in an orderly progression from normal to malignant epithelium. Since not all dysplasia become malignant, there is need to clarify the extent to which regression forms part of the natural history of dysplasia. The present study aims at seeking information on the natural history of cytologically identified but untreated dysplasia in comparison with a sample of normal women with smears examined in the same laboratory. An estimated 10,000 women in the case series of moderate or severe dysplasia and 30,000 in the control series will be included. Information is also being sought on the possible association of oral contraceptive use and the risk of progression of dysplasia. Data extraction is currently under progress.

EPIDEMIOLOGICAL STUDY OF LARYNGEAL CANCER

A.B. Miller, University of Toronto, *92 College St., Toronto, Ontario, Canada* M5S 1B2 (D-IARC-79-104)

The study is designed to investigate the contribution of known and suspected aetiological factors to laryngeal carcinoma. It is hypothesized that there is an association between laryngeal carcinoma and the smoking of tobacco and that there is a reduced risk for smokers of filter cigarettes. It is also proposed that there is a synergistic effect between alcohol consumption and the smoking of tobacco. A further hypothesis is that there is an association between laryngeal cancer and exposure to asbestos in the environment and occupationally, especially for those who smoke cigarettes. It is also hypothesized that there is an association between cancer of the larynx and exposure to nickel refining and processing. The study is a case-control study with data on past events and exposure obtained from cases and controls by means of a detailed questionnaire which is administered personally to cases and controls in their homes. The study population consists of all newly diagnosed cases with carcinoma of the larynx, March 1, 1977, to April 31, 1978, resident in Southern Ontario and the Sudbury, and North Bay areas in Northern Ontario. Controls are matched to cases by age (plus or minus five years), sex, and neighborhood of residence. Controls are obtained by door to door survey. At the end of 16 months of interviewing, a total of 130 case-control pairs have been interviewed. It is anticipated that a total of 200 case-control pairs will be available for analysis.

THE PREVALENCE OF BREAST CANCER AMONG FEMALE FACULTY MEMBERS AND FACULTY WIVES

B.J. Morrison, University of British Columbia, Dept. of Health Care & Epidemiology, *2075 Wesbrook Pl., Vancouver, British Columbia, Canada* V6T 1W5 (D-IARC-79-112)

The object is to determine the prevalence rate of breast cancer among women who are faculty members and among the wives of the male faculty members and compare it with the expected rates from provincial incidence figures. Because of their high socioeconomic class and late child bearing, this group of women may be at a high risk. The rates will be correlated with age at first pregnancy to see if there is an excess rate after correction for this has been made. All faculty members were sent a brief questionnaire and to date over 70% have responded. The data have not yet been tabulated.

ANALYSIS OF CERVIX UTERI CANCER MORTALITY RATES IN CHILE

A. Dabancens, Universidad de Chile, Servicio de Citopatologia y Control de Cancer, *1058 Av. Bernardo Ohiggins, Santiago, Chile* (D-IARC-79-115)

The study evaluates the National Cervix Uteri Cancer Control Programme. Standardized mortality rates for this cancer in different regions of the country are related to the percentage of women screened in these regions. A reduction of more than 70% in mortality rates, taking epidemiological factors into account, has been observed in the screened population. The rates per 100 00 for women over age 20 from 1970-1977 in two areas of Santiago show, for unscreened populations, expected rates of 27.90 and 24.54 and observed rates of 47.84 and 27.46, while in the screened populations expected rates are 17.40 and 19.43 and observed 4.64 and 5.71. The study continues.

CHILDHOOD CANCER AND PARENTS' OCCUPATION

K.J. Hemminki, Inst. of Occupational Health, Dept. of Industrial Hygiene & Toxicology, *Haartmaninkatu 1, SF00290 Helsinki 29, Finland* (D-IARC-79-148)

The study aims to find out whether any correlation exists between the occupational activities of parents and cancer in their children. The material consists of cancer cases in children under 15 years recorded by the Finnish Cancer Registry in 1959-1968. The parents' occupations were traced from the records of the antenatal clinics. Controls were matched for age and place of birth. The material is being analysed with regard to the occupation of the parents.

INTESTINAL MICRO-ECOLOGY IN NORDIC COUNTRIES

O.M. Jensen, Centre International de Recherche sur le Cancer, Unit of Epidemiology & Biostatistics, *150 Cours Albert Thomas, 69372 Lyon Cedex 2, France*

The project continues to collect information in relation to two sets of hypotheses: (1) Metabolic hypothesis - specific dietary consituents, e.g., fat or type of meat, are related to fecal bacterial flora, metabolities of bile acids and steroids in the feces and in turn to colon cancer risk differences. (2) Fiber deficiency hypothesis - it has been postulated that high intake of fiber (especially from cereals) results in increased fecal bulk and is protective against colon cancer. These hypotheses are being examined in a collaborative project comparing urban and rural populations in Denmark and Finland. The populations are compared in terms of present diet, including dietary fiber, mouth-anus transit time, fecal bacteria, steroids and mutagenicty, other characteristics, such as fecal weight.

DETERMINATION OF A RISK LEVEL FOR BREAST CANCER AND ITS APPLICATION TO MASS SCREENING

A.G. Bremond, Hopital Edouard Herriot, Clinique Gynecologique, *Pl. d'Arsonval, 69374 Lyon Cedex 2, France* (D-IARC-79-171)

Nationwide X-ray screening is both impracticable and unadvisable. If high risk women were identified, this

examination could be restricted to a smaller number of patients. On the basis of known epidemiological data, a double prospective survey can be carried out among cancer-free control women and those who have had breast cancer. The risk level, determined through a computer program, should select 80 percent of women with cancer and not apply to more than 50 percent of controls.

PRECANCEROUS LESIONS OF THE OESOPHAGUS IN HIGH- AND LOW-RISK AREAS FOR OESOPHAGEAL CANCER

N. Munoz, Centre International de Recherche sur le Cancer, Interdisciplinary Programme & International Liaison, *150 Cours Albert Thomas, 69372 Lyon Cedex 2, France* (D-IARC-79-179)

The objective of this study is to determine the type and prevalence of precancerous lesions of the oesophagus in populations with high and low rates of oesophageal cancer. At autopsy, oesophagi have been collected from patients dying of diseases other than cancer of the oesophagus. The specimens have been processed and examined by the pathologists participating in the study, using standard techniques. Slides from each case are being sent to the IARC for circulation among the pathologists. A blind histopathological evaluation of these will be made, using a standard protocol.

INTERDISCIPLINARY STUDIES ON NASOPHARYNGEAL CARCINOMA AND ASSOCIATED HUMAN TUMOURS

G. The, Centre National de la Recherche Scientifique, Intl Prog for Epidemiological & Exp Stud on Human Tumors, *15 Quai Anatole, 75700 Paris, France* (D-IARC-79-182)

The objective of the study is to determine the importance of Epstein-Barr virus immunovirological tests for clinical management of nasopharyngeal carcinoma. The specific aims are to evaluate IgA antibodies to EBV in serum and saliva of NPC patients as a marker for prognosis; to evaluate EBV serology and EBV markers in tumour cells as complement to pathology to characterize malignancies arising in the nasopharynx, and to evaluate EBV serology as a tool for diagnosis in metastatic cervical lymph nodes with occult primary, and as a method of early detection in areas having high incidence of NPC. The project will involve the following closely linked sub-projects: (1) a prospective study involving all new NPC patients in Paris, Milan, Tunis and most of the patients in Hong Kong, aimed at assessing the value of EBV immunovirology in the management of NPC, using clinical, pathological and experimental parameters for the evaluation of survival at three and five years after diagnosis; (2) a case-control study involving different types of tumours arising in the nasopharynx as well as in the rest of the upper respiratory tract, with the aim of assessing the strength of the association between EBV and these tumours; this will include comparison of clinical, histopathological, epidemiological and experimental data on the different types of tumours observed; (3) a sub-study in Western European centres and in Tunis to assess EBV serology as a diagnostic tool to detect NPC in patients with cervical metastatic lymph nodes with occult primary; (4) a prospective study in Hong Kong involving the family members of NPC patients to assess the value of EBV serology as a method for early detection of the disease.

LARGE BOWEL PATHOLOGY IN AUTOPSY SERIES

L. Meurman, Centre International de Recherche sur le Cancer, Unit of Epidemiology & Biostatistics, *150 Cours Albert Thomas, 69372 Lyon Cedex 2, France* (D-IARC-79-177)

GENERAL OBJECTIVES: The general objectives are to study and document in a comparable manner all lesions of the colon and rectum in adult autopsy series in different geographical areas with contrasts in large bowel incidence.

SPECIFIC OBJECTIVES: To investigate and compare the prevalence, distribution and histological types of various lesions of the colon and rectum in autopsy series in certain urban and rural populations of Europe, and where feasible in other geographical areas. Among the lesions studied, the greatest attention will be given to the macroscopic and microscopic features of mucosal lesions, i.e. various types of polyps. Other lesion studies will include cancer, diverticular disease, inflammatory disease and melanosis. In the case of diverticular disease, the emphasis will be on the description of the distribution and the presence of inflammation.

HISTOLOGY, IMMUNOPATHOLOGY, AND VIROLOGY OF MALIGNANT LYMPHOMAS (EPIDEMIOLOGICAL COMPARISON BETWEEN WEST GERMANY AND COLOMBIA)

G. Krueger, Universitat zu Koln, Immunopathology Section, *Cologne, Federal Republic of Germany* (D-IARC-79-217)

The objective of the study is to identify various histological and immunological types of malignant lymphomas and correlate their incidence with the frequency of infectious diseases in general and with EBV infection. In particular there is an obvious difference in the occurrence of various types of malignant lymphomas between West Germany and Colombia. There also appears to be a difference in the incidence of infectious diseases between both countries, both bacterial and viral. It is expected that certain types of malignant lymphomas will increase with the increased frequency of infections. The study will identify such tumours and analyse their pathogenesis by comparing the results with those from experimental studies on lymphomagenesis.

THE PROPORTION OF METAL WORKERS AMONG PATIENTS WITH TESTICULAR CANCER AND AGE-MATCHED CONTROLS

W.U. Rhomberg, Medizinische Hochschule Hannover, Dept. of Radiology, *Karl-Wiechert-Allee 9, D3000 Hannover 61, Federal Republic of Germany* (D-IARC-79-210)

Preliminary analyses suggest that the occupational histories of patients with testicular cancer show an unusually high proportion of metal workers. The data have been collected from 64 patients treated in the Medizinische Hochschule between 1967 and 1974. The objectives of the present study are to increase the number of interviews investigating the occupational background of patients with testicular cancer, and to establish a control group consisting of patients with diseases other than cancer, of comparable age and treated in the same hospital as the patients with testicular cancer.

RISK OF SOMATIC RADIATION DAMAGE - EPIDEMIOLOGICAL INVESTIGATIONS ON RADIATION DAMAGE IN PATIENTS TREATED WITH RA-224

W. Goessner, Gesellschaft fuer Strahlen und Umweltforschung mbH Munchen, Abteilung fuer Pathologie, *Ingolstaedter Landstrasse 1, 8042 Neuherberg, Federal Republic of Germany* (D-IARC-79-228)

In about 2,000 persons treated with radium-224 for ankylosing spondylitis (Bechterew's Disease) or bone tuberculosis, the effects of this particular type of radiation are being investigated. In collaboration with orthopedic hospitals the patients are subjected to follow-up examination. The results of these investigations, in particular the onset of malignant and degenerative disease and causes of death, are evaluated with a view to establishing dose-response. Further knowledge about the risk of radiation cancers in general is thus gained.

STUDY OF THE POSSIBLE PREVENTIVE EFFECT OF BCG AGAINST CANCER IN ADULTS

L. Frappier Davignon, Armand Frappier Institut, Centre de Recherche en Epidemiologie et Medicine Preventive, *531 Blvd. des Prairies, Case Postale 100, Laval des Rapides, Quebec, Canada* H7N 4Z3

Studies have shown that BCG may have a non-specific preventive effect against mortality due to leukemia in children aged 0 to 4 years. This cohort study aims to determine if BCG could have a preventive effect against cancer in adults by comparing mortality and morbidity from cancer of all types among vaccinated and unvaccinated nurses. Names and addresses of all nurses graduated in the Province of Quebec between 1952 and 1967 were obtained. A questionnaire was sent to each. This questionnaire included questions on age, date of graduation, marital status, BCG vaccination status, names of diseases of all kinds diagnosed since graduation, date of the event, place of diagnosis and treatment, name of physician, smoking habits, number of pregnancies and abortions and finally name and cause of death of classmates known to have deceased since graduation. The BCG vaccination status was verified in the central BCG record of l'Institut Armand-Frappier. Information has been received from 12,856 nurses of a possible total of 21,000, and 453 deaths have been reported. These data will be analyzed, taking into consideration vaccination status, age and time since vaccination.

CONGENITAL MALFORMATIONS AND NEOPLASMS IN NEWBORNS AND INFANTS

M. Hauge, Odense Universitet, Inst. of Clinical Genetics, *17 Winslowsvej, 5000 Odense C, Denmark* (D-IARC-79-139)

A ten per cent sample of the population of Denmark is being followed from birth through infancy to provide incidence and prevalence figures for congenital malformations and malignant growths. Sources of information include: hospital case records, midwives' reports, death certificates and postmortem reports. Within the area selected all cases having been diagnosed as neoplasms will be traced. Basic population data are available in great detail.

CASE-CONTROL STUDY IN COPENHAGEN OF URINARY BLADDER TUMORS

J. Clemmesen, Finseninstitutet, Danish Cancer Registry, *Strandboulevarden 49, DK2100 Copenhagen, Denmark* (D-IARC-79-130)

The aim is to undertake a case-control investigation of factors associated with lower urinary tract cancers in Copenhagen (bladder, renal pelvis, ureter, urethra). The following factors will be investigated: tobacco smoking, diet, with particular regard to intake of coffee and artificial sweeteners, use of drugs, in particular analgesics, and occupation. Qualitative and quantitative exposure among newly diagnosed cases (500) will be compared with two independent age-matched and sex-matched control groups drawn from among hospital patients (500) and the total population (1,000), respectively.

REGISTRATION OF WOMEN WITH PRIMARY AND SECONDARY GENITAL HERPES SIMPLEX VIRUS (HSV) INFECTION

B.F. Vestergaard, Kobenhavns Universitet, Inst. of Medical Microbiology, Dept. of Clinical Virology, *22 Juliane Mariesvej, DK2100 Copenhagen OE, Denmark* (D-IARC-79-136)

Recent observations indicate that women suffering from primary genital HSV type 2 infection represent a high risk group for later development of carcinoma of the uterine cervix. The development of a simple, sensitive and reliable enzyme-linked immuno-specific assay (ELISA) for the exact titration of herpes simplex virus type 1-and type 2-specific antibodies in human sera has made it possible to perform serological HSV type-specific diagnosis of clinical cases of genital HSV infections and identify four categories of patients: (1) primary genital herpes caused by HSV type 2 (HSV infection in an individual who has never had an HSV infection before); (2) primary genital herpes caused by HSV type 1; (3) secondary genital herpes caused by HSV type 2 (genital HSV in an individual who has previously had an HSV type 1 infection); (4) wrong clinical diagnosis (i.e., the serological result indicates that the patient did not have an HSV infection). It is planned, in a period of three years, to diagnose and register as many of the genital HSV infections as possible - hopefully at least 50% of all cases in Denmark seeking medical care. The later follow-up of the registered cases of genital HSV infection will be performed under the screening programs for cervical carcinoma presently being developed in Denmark. The objective of the study is, by a large-scale prospective investigation, to obtain valid information about: (1) The incidence of genital HSV infection in Denmark and the distribution of primary and secondary cases, and (2) the risk of later development of carcinoma of the uterine cervix.

A RETROSPECTIVE STUDY OF CANCER IN RELATION TO A SPECIFIC ENVIRONMENTAL FACTOR - WATER NITRATE

C. Conrad, KAS Herlev, Dept. of Radiotherapy & Oncology, *Herlev Ringvej, 2730 Herlev, Denmark* (D-IARC-79-138)

The incidence of testis cancer in Denmark has for years been known to exceed that of neighbouring countries (6.0 new cases/year/100,000 males). In this study a small, geographically limited 'hot-spot', possibly of recent origin, with an incidence of 31.7 new cases/year/100,000 males during the last 2 years (01-06-76 - 01-06-78) has been detected. This particular region differs from the rest of the island of Sjaelland (the island where the capital Copenhagen is situated) in one specific respect: the content of nitrate in deep ground-water supplies. The possibility of the formation of carcinogenic nitrosamines from nitrate, nitrite and secondary amines in humans is being examined. Data are now being collected to determine if there is significant rise in the incidence of other cancers, particularly bladder cancer.

EPIDEMIOLOGIC STUDIES ON MALE LUNG CANCER IN NORTHERN SWEDEN

L.G. Larsson, Regionsjukhuset, Dept. of Oncology, *58185 Linkoping, Sweden* (D-IARC-79-524)

In a study of the geographical distribution of all new male lung cancer cases in the three northernmost counties in Sweden between 1959 and 1971 great differences were found between different regions. Some communities with mining districts or other heavy industry had age-adjusted incidence rates 10-15 times higher than more rural communities. The occupational profile of te cancer cases is being compared with that of a control series matched by age and place of residence. Information about occupa-

tion is obtained both for the cases and for the randomly selected controls through the general population register. For deceased male lung cancer cases registered in the same region from 1972 to 1977, a more detailed case-control study is being performed based on questionnaires to relatives about occupation, employment and smoking habits.

MORTALITY OF SMOKERS AMONG SWISS PHYSICIANS

O.R. Gsell, Universitaet Basel, Dept. fuer Innere Medizin, *Zwinglist. 21, 9000 St. Gallen, Switzerland* (D-IARC-79-530)

The mortality rates and causes of death for smokers, nonsmokers, and past smokers in Swiss physicians have been examined as part of a study of 1,212 deaths in 3,740 physicians from 1955-1973. All of the 40 doctors with bronchial carcinoma were smokers. The death rate for myocardial infarction in smokers was high for the age-group 35-55, returning to normal over the age of 75. The similarity of mortality rates in cigar and pipe smokers in Switzerlnd with those of non-cigarette smokers (around 20% of the total) is of special interest. The study continues.

POSTMENOPAUSAL OESTROGEN TREATMENT AND ENDOMETRIAL CANCER

I.R. Persson, Uppsala Universitet, Dept. of Obstetrics & Gynecology, *Box 256, S75105 Uppsala, Sweden* (D-IARC-79-526)

It has been hypothesized that oestrogens are related to development of postmenopausal endometrial cancer. Numerous American case-control studies have shown a substantial increase of risk in connection with oestrogen replacement therapy. The present study is a prospective one which will follow a sample of some 30,000 oestrogen-treated postmenopausal women during an observation period of at least five years to ascertain the incidence of endometrial cancer. The observed incidence in this cohort will be compared to the expected one which will be computed from available cancer statistics. There will be additional studies in this cohort regarding the incidence of mammary cancer and also deep vein thrombosis and gallbladder disease. The large cohort is established by collecting all oestrogen prescription forms from a defined geographical region in the center of Sweden. From these prescription forms the identity-number (a ten-digit number) will be collected and stored with the help of computer facilities. All new cases of endometrial cancer will be collected from different pathology departments which serve the same geographical region. All hysterectomized women in the cohort will be excluded by referring to a special computer-based admission diagnoses register. All cases of endometrial cancer will be examined and interviewed to study the distribution of known risk factors. This will be done in samples of the total oestrogen cohort and samples from a non-treated healthy population.

THE EFFECT OF GYNECOLOGICAL SCREENING PROGRAMS ON THE INCIDENCE OF CERVICAL NEOPLASIA

L.G. Lindberg, University Hospital of Lund, Cytodiagnostic Laboratory, *E. Blocket, S22185 Lund, Sweden* (D-IARC-79-511)

Cytological screening programs have a certain effect on the incidence figures of cervical neoplasia, both pre-invasive and invasive. However, a significant effect on mortality figures has been difficult to establish. Using a computerized program and the unique person identification number long accepted by everyone in Sweden, every single investigation and single individual can be easily followed. Preliminary figures indicate that a significant effect can be demonstrated much earlier than previously found among women actively taking part in a screening program.

2.1899,

EXPOSURE TO IRON OXIDE AND CANCER INCIDENCE

O. Axelson, University of Linkoping, University Hospital, Dept. of Occupational Medicine, *58185 Linkoping, Sweden* (D-IARC-79-509)

Several epidemiological and experimental reports suggest that iron oxide is carcinogenic. However, the reported increase in lung cancer mortality among the various populations (miners, foundry workers) with exposure to iron oxide might be due to concomitant exposures, e.g., randon daughters in the mines, polycyclic hydrocarbons in the foundries, etc. High levels of exposure to iron oxides have occurred in a Swedish plant producing sulphuric acid from pyrites. This situation provides another opportunity to evaluate the possible cancer hazard of iron oxides. This is a case-control study, using two controls for each case matched by sex, age and place of residence. It is undertaken within a general evaluation of the relationship between cancer and various occupational exposures in the city of Helsingborg.

2.1900,

HERBICIDE EXPOSURE AND CANCER INCIDENCE AMONG RAILROAD WORKERS

O. Axelson, University of Linkoping, University Hospital, Dept. of Occupational Medicine, *58185 Linkoping, Sweden* (D-IARC-79-508)

An earlier report (Axelson and Sundell, Work Environ Health 11, 21-26, 1974) indicated a cancer hazard due to exposure to amitrole. Further evaluation has shown that exposure to phenoxy acids might also produce cancer (Axelson, Scand. J. Work Environ Health 4,85-89, 1978) and this is confirmed in another recent study on mesenchymal tumors and exposure to phenoxy acids and chlorophenols (Hardell, Laekartidnignen 75, 3535, 1978). It seems pertinent, therefore, to update the earlier study of a cohort of railroad workers to find out whether or not the increased cancer mortality continued after 1972.

MORTALITY AMONG FOREST WORKERS

O. Axelson, University of Linkoping, University Hospital, Dept. of Occupational Medicine, *58185 Linkoping, Sweden*

Several studies have shown an increased risk of cancer among people with exposure to various herbicides. Forest workers in Sweden have used phenoxy acids since the beginning of the 1950s and an evaluation of the mortality pattern might show particular features. The study will be descriptive in character and will show the proportional mortality for various causes of death. About 1,030 forest workers are known to have died during the study period, 1968-1977, as recorded on union registers. Using case-control techniques, a second part of the study will examine cause-effect relationships between cancer and exposure to phenoxy acids.

2.1902,

MINING, SMOKING AND LUNG CANCER

O. Axelson, University of Linkoping, University Hospital, Dept. of Occupational Medicine, *58185 Linkoping, Sweden*

An earlier report (Axelson and Sundell, Scand. J. Work Environ. Health 4, 46-52, 1978) has indicated a greatly increased lung cancer incidence among zinc-lead miners, as has also been found for iron ore miners in Sweden. It seems resonable to suppose that the occurrence of radon and radon daughters in the mines is primarily responsible for the increased lung cancer mortality among miners. Surprisingly it was found that non-smokers were affected as much or even more than smokers, although smokers, on an average, died of lung cancer before the age of 60, whereas non-smokers died over the age of 70. The explanation might be that smokers in underground work tend to get bronchitis, i.e. an increased thickness of the mucosa, which might protect against alpha radiation. Other mining groups are now being studied using a similar technique to confirm or refute earlier findings.

CANCER OF THE BLADDER IN OPIUM ADDICTS

S. Behmard, Pahlavi University, School of Medicine, Dept. of Pathology, *Shiraz, Iran*

The main result of a case-control study of patients with bladder cancer at Shiraz (Pahlavi) University Hospitals was that the risk of developing cancer of the bladder in opium addicts is at least eight times greater than that of the normal population. A prospective study with screening of all opium addicts (by urine cytology for detection of early bladder carcinoma) was thus started at the University. The preliminary results indicate that the risk of developing cancer of the bladder is considerably higher in opium addicts than previously assumed. As of July 1978, 3,500 opium addicts had been screened. The controls, who do not take opium, number 1,750 and are matched by age and sex. A history of smoking habits is obtained. Fourteen histologically confirmed and previously unrecognized cases of bladder cancer have been detected. This early finding indicates that opium addiction should be considered as a carcinogenic agent for cancer of the bladder and further investigation is warranted. Schistosomiasis has not yet been reported in Fars Province and there is little industry.

MALIGNANT LYMPHOMA (NON-HODGKIN'S) IN EAST-JAVA

D.S. Hoediasmoro, Universitas Airlangga, Faculty of Medicine, Dept. of Pathology, *Jalan Dharmahusada No. 47, Surabaya, East Java, Indonesia* (D-IARC-79-281)

A retrospective study of non-Hodgkin's Malignant Lymphoma (nHML) in the Department of Pathology, Faculty of Medicine, Sourabaya (1973-1976) gave rise to a number of problems. There were many difficulties in investigating possible aetiological factors on nHML. The only factor that could be investigated and regarded as probably having an aetiological correlation was the socio-economic status of the nHML case. The possible correlation between the subtypes of nHML and their response to a certain mode of therapy was difficult to evaluate for various reasons including a limited budget. The study design has been changed and it is now intended to report the relative frequency of sub-types of nHML (histopathological classification), to investigate the age-distribution, to investigate the possible relation with socio-economic levels, and to investigate the geographical distribution. To increase the number of samples investigated, the anatomical site under study has been extended to the whole reticuloendothelial system and the area investigated has been enlarged from the Sourabaya area (town) to East-Java (province).

THE SWEDISH CANCER ENVIRONMENT REGISTRY

K. Wiklund, National Board of Health & Welfare, Planning Div., *Linnegatan 87, 10630 Stockholm, Sweden* (D-IARC-79-521)

The persons with tumours who are entered in the Swedish Cancer Environment Registry are those contained in the Swedish Cancer Registry for a period 1961-1973 and verified as being registered in the 1960 Population and Housing Census. During the period from 1 January 1961 to 31 December 1973, the number of cases of cancer at sites 140-205 in the Registry was 376,015. Individuals were indentified by their personal identification number. On linking the files one per cent of entries in the Cancer Registry could not be traced. The information entered in the Registry, obtained from the 1960 Population and Housing Census, concerned the following: occupation, main occupation during the year, economic activity, occupational status, gainful employment, county, municipality or parish, location of place of work (county, municipality, parish), country of birth and education.

STUDY OF UTERINE CERVICAL DYSPLASIA AND ITS RELATION TO CERVICAL CANCER (SQUAMOUS CELL) - CLINICAL, CYTOPATHOLOGICAL AND VIROLOGICAL

P. Seth, All India Inst. of Medical Sciences, Dept. of Microbiology, *Ansari Nagar, New Delhi 110016, Delhi, India* (D-IARC-79-278)

Evidence on the aetiopathogenesis and biological behavior of cervical dysplasia is mostly controversial. However, it is generally cases of cervical dysplasia which progress to squamous cell carcinoma. A multifaceted approach to the study has been planned in two phases, the first collecting data on the clinical, cytopathological and virological status of dysplastic lesions and cervical cancer and the second to follow up a sizable number of dysplasia cases with adequate controls to understand the biological behavior of the lesions and their progression to cervical cancer. A minimum number of 300 cases of dysplasia and 200 cases of cervical cancer will be registered along with similar numbers of matched controls. These cases and controls will be followed up every 6 months for a minimum period of 5 years. At each follow-up cervical swabs will be collected for cytology (biopsy will be taken from the patients with dysplasia whenever possible). In addition, sera will be collected and screened for herpes simplex virus type 1 and 2 antibodies.

CANCER REGISTRY IN EASTERN INDIA

J.R. Chowdhury, Chittaranjan National Cancer Research Centre, Dept. of Epidemiology, *37 S.P. Mukherjee Rd., Calcutta, 700026, West Bengal, India* (D-IARC-79-271)

There is no comprehensive cancer registry in Eastern India (West Bengal, Bihar, Assam and Orissa). Cancer patients from these states belonging to various groups with different socio-economic characteristics are referred to cancer hospitals and other hospitals of Calcutta for treatment. A cancer registry has been set up at the Epidemiology Dept. of Chittaranjan National Cancer Research Centre, Calcutta, to provide data for studying aetiology, epidemiology, treatment and end results of malignant diseases. The basic objectives of this registry include: (1) study of frequency distribution of different types of cancer in this area; (2) definition of high risk profiles; (3) determination of trends and aetiological factors.

CHRONIC ATROPHIC GASTRITIS AND INTESTINAL METAPLASIA IN THE HUNGARIAN AND ITALIAN POPULATIONS

A. Bajtai, Postgraduate Medical School, Dept. of Pathological Anatomy, *Szabolcs u. 33/35, 1389 Budapest, Hungary* (D-IARC-79-241)

Stomach cancer is very frequent in Hungary. The most important predisposing conditions are chronic peptic ulcer, chronic atrophic gastritis with or without intestinal metaplasia and gastric polyps. The main objectives of the study are to identify any links between these high risk lesions and gastric cancer, and the relation of these precancerous conditions to each other. It is proposed to undertake comparative studies in Italy including nitrosamine levels in gastric juices and their relation to the histological alterations of the stomach. Some 200 patients with the listed conditions are being followed as well as non-symptomatic controls.

OESTROGEN PROFILES IN DAUGHTERS OF BREAST CANCER PATIENTS IN GREECE

D. Trichopoulos, University of Athens, School of Medicine, Dept. of Hygiene & Epidemiology, *Odos Panepistimiou 30, Athens 609, Greece* (D-IARC-79-234)

To account for the major features of the epidemiology of breast cancer, a hypothesis has been developed linking breast cancer risk to oestrogen metabolism. The hypothesis postulates that women who, during the early years of reproductive life, metabolize a low proportion of their oestrogen to oestriol are at

high risk of breast cancer during the remaining years of their lives. Since daughters of breast cancer patients are at increased risk of breast cancer, it should be expected that these women would have low oestriol ratios. Urine samples are being collected from 100 daughters of breast cancer patients hospitalized in Athens. Oestrogen profiles and other hormone metabolites are being measured in Melbourne or Boston.

2.1917,

CANCER MORTALITY ALONG A TRAFFIC ARTERY

W. Blumer, (No Performing Organization Reported), *Switzerland* (D-IARC-79-537)

During an observation period of 18 years it was found that cancer mortality among all persons living adjacent to a highway was six times higher than that of the inhabitants of a traffic-free quarter. The soil content of polycyclic hydrocarbons along the traffic artery was 12 times greater than in the traffic-free section, and it could be proved that these hydrocarbons originated from automotive emissions. In the course of the next few years the condition of the still surviving inhabitants adjacent to the traffic artery will be examined. The possibility that other factors could be responsible for the excessive frequency of deaths due to cancer along the traffic artery will also be considered. Further analyses will determine whether a decrease in emissions and therefore decrease in cancer mortality take place.

AETIOLOGY OF PRIMARY SARCOMAS AND PULMONARY HAMARTOCHONDROMAS

C. Gebauer, Johannes Gutenberg Universitat Mainz, Medical Clinic, *Langenbeckstrasse 21, D6500 Mainz, Federal Republic of Germany* (D-IARC-79-145)

The relation between carcinogenic exposures and the 104 pulmonary hamartochondromas diagnosed in 1959-1974, 192 histologically typed carcinomas of the lung in 1961 and 41 primary pulmonary sarcomas diagnosed between 1957 and 1974 in the regional pulmonary clinic of Zschadrass is being assessed. Controls are selected from a defined district, near Leipzig, with 35,300 inhabitants aged 20-80 years, which is within the area served by the clinic. This area contains an urban residential district, a rural area, and an industrial zone. Among the factors considered are the smoking of cigarettes; air pollution as determined by residence in urban, rural and industrial areas; exposure to radiation in underground mining; chronic lung diseases, notably chronic bronchitis, tuberculosis and silicosis; family history of cancer; blood groups. The various histological types of lung cancer are compared with the sarcomas and hamartochondromas.

BURKITT TUMOUR PROJECT

F.K. Krumah, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, Viral Oncology Section, *Accra* (D-IARC-79-230)

For more than on decade many aspects of research into Burkitt's lymphoma have been studied at this centre. Tumour specimens are provided to research groups and a serum bank on all patients throughout their illness is maintained. Epidemiological studies have included geographical variation and a longitudinal follow-up of the natural history of Epstein-Barr Virus infections. Current studies include HL-A typing of patients and controls and cross sectional serosurveys for malaria and EBV antibodies among rural and urban populations.

COMPARATIVE STUDY OF ALCOHOLISM AND CANCER OF THE HEAD AND NECK

W.S. Lowry, Queens University of Belfast, Dept. of Oncology, *Belfast, Northern Ireland, United Kingdom*

One hundred patients with a diagnosis of head and neck cancer were investigated carefully for a history of alcoholism in the U.S.A. Most patients with cancer of the tongue, tonsil and oropharynx were alcoholics. About one half of the patients with supraglottic carcinoma were alcoholics. In the nasopharynx and true vocal cords, there was no association with heavy drinking. The study is now being extended to Ireland since the Irish ethnic group allegedly accounts for a considerable proportion of the American drinking problem. Initial results suggest that this may be exaggerated at least as far as the cancer problem is concerned.

A CASE-CONTROL STUDY ON CANCER AND MALFORMATION IN CHILDHOOD

R. Puntoni, Universita degli Studi di Genova, Inst. de Oncologia, Dept. of Epidemiology, *Viale Benedetto 15, Pad. B, 16132 Genoa, Italy* (D-IARC-79-320)

The aim of this investigation is to study the relationship between cancer and malformation and maternal exposure to suspected carcinogens (event or factor) during pregnancy. All the cases of cancer and malformation seen at Gaslini Hospital in Genoa for the period 1972-78 (about 500) have been collected. A random sample of children of the same age and sex with different diseases in the same hospital will constitute the control group.

ASBESTOS-RELATED CHEST DISEASES IN BEDIRLI-YESILOVA-BURDUR

Y.I. Baris, Hacettepe Universitesi, Faculty of Medicine, Dept. of Chest Diseases, *Ankara, Turkey* (D-IARC-79-551)

Bedirli is a village with a population of 643, located in southern Turkey, in the region of the lakes. Preliminary mineralogical studies show that there are tremolite type asbestos fibers in the soil and the white stucco used in the village. 200 people (112 males and 88 females) between 25 and 80 years of age were surveyed. The mean age was 44.4. Pleural, diaphragmatic and pericardial calcified plaques were found in 26 percent; 32.9 percent among males and 20.5 percent among females. Pleural thickening was seen in some of the cases with pleural calcification and in 8 percent of the total population without calcified pleural plaques. This population is being followed to assess risk of mesothelioma and lung cancer.

EPIDEMIOLOGICAL ASPECTS OF ASBESTOSIS AND MALIGNANT TUMORS

S. Yazicioglu, Diyarbakir University, Medical Faculty, Dept. of Chest Diseases, *Diyarbakir, Turkey* (D-IARC-79-556)

Chrysotile asbestos, freely dug, sold and used by inhabitants of some villages and towns in Turkey, leads to pleural calcification with the eventual complication of malignancy of the respiratory tract. This study aims to gather information concerning malignancies of the upper and lower segements of the respiratory tract and, to some extent, of the digestive system in people of different socioeconomic levels and geographic regions. The biological effects of asbestos will also be investigated in both humans and animals using clinical, experimental and laboratory methods, electron microscopy and mineralogical analysis of the biological material. The groups to be studied are: (1) hospital cases; (2) cases found in screening of the field; (3) animals such as mules and asses (used for transport); (4) laboratory animals such as rats and rabbits. Air and water pollution studies will also be carried out. This study will involve large control groups. Since Turkey is rich in different minerals, this investigation will reveal similar effects, if any, of other elements.

RELATION BETWEEN REGIONAL DIETARY FIBER AND NUTRIENT INTAKES AND COLON CANCER MORTALITY IN GREAT BRITAIN

R. Williams, Medical Research Council, Dunn Clinical Nutrition Centre, *Trumpington St., c/o Addenbrookes Hospital, Cambridge CB2 1QE, England, United Kingdom* (D-IARC-79-580)

There have been suggestions that the intake of dietary fiber is protective against neoplasms of the colon. Previous reports have dealt with international comparisons using estimates of crude fiber intake based on food production figures. This investigation explores associations between fiber intake and cancer of the colon within a defined region (Scotland, England and Wales). Figures for total dietary fiber consumption and the consumption of the components of fiber on a regional basis are computed from the National Food Survey estimates of food consumption (1969-73) and the fiber analyses of Southgate. Figures for nutrient intake and the consumption of certain foodstuffs are also included in the analysis. These are compared with truncated age-standardized death rates from cancer of the intestine (excluding rectum) for the same period.

A FOLLOW-UP STUDY OF WORKERS IN FLAX MILLS

P.C. Elwood, Medical Research Council, Epidemiology Unit, *4 Richmond Rd., Cardiff CF2 3AS, Wales, United Kingdom* (D-IARC-79-581)

The aim of the study is to relate mortality in flax workers to occupation and dust exposure over a 16 year period. In 1962 a study was conducted by Elwood and others of 2,528 flax workers employed in Northern Ireland. A modified form of the Medical Research Council questionnaire was administered, simple respiratory measurements were made and a detailed survey of dust levels was conducted. An attempt is now being made to trace each worker seen in 1962. If dead, the certified cause of death will be ascertained and related to occupation, dust exposure and probably some of the measurements made in 1962.

MONOGRAPHS ON CLINICAL AND EPIDEMIOLOGICAL ASPECTS OF MALIGNANT DISEASE IN A POPULATION OF 5 MILLIONS

J.A. Waterhouse, Regional Cancer Registry, *c/o Queen Elizabeth Med. Ctr., Birminghan B15 2TH, England, United Kingdom* (D-IARC-79-577)

A series of monographs is being prepared, each one dealing with a single site, or with a group of closely related sites, where, by examining at the same time both epidemiological and clinical features in extenso, an attempt is made to provide an overall view of the occurrence and treatment of the disease in the region as a whole. By including all cases, rather than a selected series from a central hospital, the degree of variation of treatment and survival can be shown. One of the results it is hoped to obtain is an improved sense of regional solidarity, leading to greater interest and participation in region-wide schemes to up-grade treatment standards and thus improve prognosis. Comparisons of incidence by geographical or other subdivisions of the region can also be used as possible indicators of etiological factors.

CORRELATIONS BETWEEN DIETARY FACTORS AND PRE- AND POST-MENOPAUSAL BREAST CANCER

B. Modan, Chaim Sheba Medical Center, Dept. of Clinical Epidemiology, *Bitan 27, Tel Hashomer, Ramat Gan, Israel* (D-IARC-79-312)

Epidemiological studies have shown the possible role of nutritional patterns in the etiology of breast cancer. Our study will try to determine the role of diet and/or nutritional status in the incidence, pathogenesis and natural history of pre- and post-menopausal breast cancer. This study is based on 720 newly diagnosed cases of cancer of the breast and 1,440 matched controls. Each case will be matched to two types of control: (1) non-malignant and non-gastrointestinal surgical patients from the same wards and (2) neighborhood. Controls will be matched on age and year of immigration to Israel (within five years), and country of origin. Analysis will be done separately for the main ethnic groups, as well as for pre- and post-menopausal women. Correction for such factors as age at first pregnancy, parity, weight, and height will be applied. A list of 243 food items will be included in the questionnaire, comparison of cases and controls will pertain to: (1) individual food items and (2) groups of foods combined on the basis of common nutritional components.

EPIDEMIOLOGICAL STUDY OF GASTROINTESTINAL CANCER

B. Modan, Chaim Sheba Medical Center, Dept. of Clinical Epidemiology, *Bitan 27, Tel Hashomer, Ramat Gan, Israel* (D-IARC-79-313)

A case-control study has been conducted on 167 stomach cancer and 300 intestinal cancer cases (198 colon cancer, 73 rectum and 25 other intestinal cancers). There were two matched controls. An increased consumption of starches among the patients with gastric cancer, and a decreased consumption of fiber among patients with colon cancer has been demonstrated. Other environmental factors, such as smoking habits, bowel habits, diet, past illnesses, occupation and years of study, past concentration camp history and symptomatology related to the cancer are being analyzed as well as assessment of characteristics related to survival.

ROLE OF INFANT FEEDING PRACTICES AND ENVIRONMENTAL FACTORS IN DEVELOPMENT OF THE GUT FLORA

B.S. Drasar, University of London, London School of Hygiene & Tropical Medicine, Dept. of Medical Microbiology, *Keppel St., London WC1E 7HT, England, United Kingdom* (D-IARC-79-614)

Studies in which the diet of individual adults has been changed, have failed to demonstrate those alterations in the flora that were expected as a result of comparisons of people in low and high colon cancer risk areas. The role of breast feeding, diet at weaning and environment in the establishment of the adult flora is being examined. The hypothesis being tested predicts that the flora detectable in adult life is the result of early feeding practices and once established is very resistent to change. Thus the metabolic potential of the flora and hence colon cancer risk would be fixed early in life. Breast fed infants and post weaning children in Malumfashi, Nigeria are compared with those in London, United Kingdom. Nutritional and environmental assessments are also being undertaken. Breath methane in children and adults are being evaluated as epidemiological indicators.

BREAST CANCER MORTALITY CHANGES IN A SCREENED POPULATION

B.A. Thomas, Jarvis Breast Screening, *Stoughton Rd., Guildford, Surrey, United Kingdom* (D-IARC-79-594)

In the Guildford Breast Screening Project, one the British Breast Cancer Screening Trials, some 25,000 women aged 45-65 are being invited to attend screening centers (fixed and mobile) for clinical examination of the breasts and mammography using the Medichrome low radiation dosage system. General practitioner age/sex registers are being used as the basis for the recruitment of all women in the age group. Personal and medical data, particularly obstetric, breast feeding, and hormonal histories, past breast problems and family histories of breast cancer are being obtained from each woman. These invitations will be repeated two-yearly from updated registers with clinical examination only, carried out by a specially trained nurse, undertaken in the intermediate years. The doctors carrying out the main screening examinations will also read the mammograms, which will be classified according to Wolfe's duct patterns with a view to the determination of mammographic high risk groups. Prevalent, incident and interval cancers will be studied and long-term follow-up undertaken. Mortality rates in this district will be compared with those in other trial and control districts.

THE INFLUENCE OF HORMONE REPLACEMENT THERAPY ON THE INCIDENCE OF BREAST CANCER IN WOMEN

A.M. Stark, Queen Elizabeth Hospital, Dept. of Gynaecological Oncology, *Gateshead NE9 6SX, Tyne & Wear, United Kingdom* (D-IARC-79-589)

The demand by women for hormone replacement therapy is increasing. Breast cancer is acknowledged to be hormone-dependent. This is a long-term project to assess the influence of hormone replacement therapy on the incidence of breast cancer in women. A cohort of 300 women is being screened for breast cancer by clinical examination, thermography and mammography before commencing hormone replacement therapy and re-examined at three months and annually thereafter. The control group consists of 300 women matched for age, parity, hormonal status, and family history of breast cancer.

HIGH INCIDENCE OF CATTLE CANCER - POSSIBLE INTERACTION BETWEEN ENVIRONMENTAL CARCINOGEN AND PAPILLOMA VIRUS

W.F. Jarrett, University of Glasgow, School of Veterinary Medicine, Dept. of Veterinary Pathology, *Bearsden Rd., Glasgow G61 1QH, Scotland, United Kingdom* (D-IARC-79-593)

The objective is to study the possible co-carcinogenic effects of papilloma virus and bracken fern in inducing alimentary cancer and urinary bladder tumours in cattle. High incidence areas in the upland beef farms of Britain have been demonstrated and the overall incidence in beef cows appears to be of the order of 2.5 to 5 percent per year. high percentage of these animals have pre-existing multiple alimentary papillomas. Virus has been extracted, purified and transmitted from these. An epidemiological study of the farms is in progress to elucidate the latent periods for papilloma induction and to attempt

to clarify the sequential stages of cancer development. The relationship between these cancers and human cancers is being examined to determine whether an increased risk is observed in affected farms.

EPIDEMIOLOGY OF BLADDER CANCER IN WEST YORKSHIRE

R.A. Cartwright, Yorkshire Regional Cancer Org., *Leeds LS16 6QB, England, United Kingdom* (D-IARC-79-598)

Yorkshire has one of the highest mortality rates in the United Kingdom for bladder cancer with an SMR for males in 1969-73 of 114. Incidence and mortality are unevenly distributed within the area and the aim of the project is to account for the high mortality and the variation in incidence. The study is a case-control investigation of prevalent and incident cases for certain hospital areas within the Yorkshire area, including Bradford and Kirklees. The controls are neighbourhood and hospital in type. A questionnaire has been constructed which explores personal habits, past medical history and occupational history in depth. Details of the natural history of the bladder cancer are also recorded. The first phase of the study, dealing with prevalent cases, will be complete in 1979, whilst the incidence study will continue for some years beyond that date. It is hoped that at least 600 cases will be interviewed in the first phase of the study.

AGE-TIME-COHORT ANALYSES OF MORTALITY

J.C. Barrett, University of London, London School of Hygiene & Tropical Medicine, Dept. of Medical Statistics & Epidemiology, *Keppel St., London WC1E 7HT, England, United Kingdom* (D-IARC-79-604)

This method of mortality analysis was first described in J. Hygiene (Camb.) 71, 253-59, 1973. It consists of the simultaneous use of age, time and cohort factors. Of the three factors, age at death, epoch of death and epoch of birth, one seems almost superfluous. It is nevertheless worthwhile to include all three, allowing for the constraints that the redundancy imposes. This procedure is being applied to published data for England and Wales on breast cancer, bladder cancer and prostate cancer mortality, 1951-1970.

A RETROSPECTIVE COHORT STUDY ON MALIGNANT NEOPLASMS IN WORKERS OF A CHROMATE MANUFACTURING PLANT IN TOKYO

T. Okubo, Jichi Medical School, Dept. of Environmental Health, *3311-1 Yakushiji, Minami, kawachi-machi, Tochigi-ken 32904, Japan* (D-IARC-79-399)

The plant chosen for study is the larger of the two chromate manufacturing plants in Japan. In recent years, 24 lung cancer cases have been reported among the chromate workers of the plant. Since the plant was in continuous operation during the period 1915-1975, the follow-up period of over 50 years is longer than that of previous reports. Various types of personnel records as well as payrolls were used to create the cohort; follow-up is carried out by the Japanese family registration system 'koseki'. Measurements of the working environment have been conducted in the plant since 1958, and it is expected that this study will show clearly any dose-response relationship.

MORTALITY STUDY OF ASBESTOS FRICTION WORKERS

M.L. Newhouse, University of London, London School of Hygiene & Tropical Medicine, T.U.C. Centenary Inst. of Occupational Health, *Keppel St., London WC1E 7HT, England, United Kingdom* (D-IARC-79-635)

This is an old established plant chiefly devoted to the manufacture of brake linings. Apart from two periods of approximately two years each, more than 30 years ago, only chrysotile asbestos has been used. Identification data on current and past employees are available, and with the assistance of the National Register the vital status of past employees will be established and the cause of death, as stated on the death certificate, ascertained. Mortality in this population will be compared with that of the population of England and Wales. Dust estimates are available only since 1969 but by means of simulation experiments dust exposure at various times will be estimated and a case-control study of deaths from lung cancer will be undertaken following the methods of Liddel and Macdonald.

CANCER AND THE INDUSTRIAL ENVIRONMENT

O.L. Lloyd, University of Dundee, Ninewells Medical School, Dept. of Community & Occupational Medicine, *Dundee DD1 9SY, Scotland, United Kingdom* (D-IARC-79-586)

Environmental influences, many of them industrial, have been held to be responsible for the vast majority of human cancers. This study aims to analyze the patterns of mortality within relatively small populations in Scotland to identify areas where the incidence (or mortality) of specified cancers is abnormally high. It is intended to investigate the environment of these areas in order to try and identify possible carcinogenic factors. It is hoped that the occupational experience of the deceased can be evaluated in order to determine whether or not carcinogenic factors were in the occupational environment or in the more general environment. Evaluation of the environment will be assisted by the collaboration of the Scottish Occupational and Environmental Health Service, Ninewells Medical School, Dundee.

HASHIMOTO'S THYROIDITIS - A POSSIBLE RISK FACTOR FOR LUNG CANCER AMONG JAPANESE WOMEN

N. Maruchi, University of Tokyo, Faculty of Medicine, Dept. of Health Administration, *7-3-1 Hongo, Bunkyo-ku, Tokyo 113, Tokyo, Japan* (D-IARC-79-394)

In order to study the epidemiological association of Hashimoto's thyroiditis to malignancy, the autopsy protocols for the period of 1959-1974 were examined at the Tokyo University Hospital. The study cases consisted of 1,896 women, among whom 107 had lymphocytic infiltration and/or fibrosis in the thyroid. The study cases were classified into several groups by major cause of death including breast cancer and lung cancer. Although there was little significant relation between these changes in the thyroid and breast cancer, a significant association between the changes in the thyroid and lung cancer was identified in the autopsy study. This finding suggests that Hashimoto's thyroiditis and related changes could be a risk factor for lung cancer among Japanese women.

STUDIES ON THE ETIOLOGY OF CHILDHOOD TUMORS

H.B. Marsden, University of Manchester, Childrens Tumor Registry, *Oxford Rd., Manchester M13 9PL, England, United Kingdom* (D-IARC-79-657)

This is a population-based study on the incidence of childhood malignancy. Details of all cases of malignancy occurring in the child (0-14 years) population (approximately 1 million) in the North West Regional Health Authority have been collected since 1954. Clinical records and microscopic slides are retained for study. Time-space clustering analysis is being carried out. Factors which may be of etiological significance in childhood malignancy, with emphasis on genetic and environmental aspects, including drugs in pregnancy and parental occupation, are being investigated. A detailed study of family histories is being made with particular emphasis on congenital malformations and malignancies in family members. The quality of life in long-term survivors is being assessed.

GYNECOLOGICAL TUMOR REGISTRY

E.G. Daw, North Manchester General Hospital, Dept. of Obstetrics & Gynaecology, *Crumpsall, Manchester M8, England, United Kingdom* (D-IARC-79-653)

All gynecological tumors seen in the northern district of Manchester are registered using a standard registration form. The data collected are subjected to systematic review. A prospective review of chemotherapy regimes used for carcinoma of the ovary is being undertaken, as well as a retrospective review of carcinoma of the cervix and corpus uteri.

COMPLETENESS OF CANCER REGISTRATION

I. Leck, Christie Hospital & Holt Radium Inst., Regional Cancer Epidemiology Unit, *Wilmslow Rd., Withington, Manchester M20 9BX, England, United Kingdom* (D-IARC-79-656)

Since 1972, the data recorded for cancer patients registered with the Regional Cancer Epidemiology Unit in Mancester (covering a population of over 4 million) have included first treating hospital, hospital to which referred (if any), and dates of registration as well as of first treatment and death. Various possible measures of completeness of registration are being developed and applied to these data, including: 1) Proportion of cases registered by first treating hospital among those registered by hospital to which referred; 2) Ratio of number of cases actually registered to an estimate of the total number diagnosed, calculated on the assumption that the proportion of cases diagnosed in survivors, that is not registered, is the same as the proportion of deceased cases that is only registered because of death. Several methods of estimating the later proportion are being evaluated.

2.1960,

BLADDER. CANCER MORTALITY IN CERTAIN AREAS AND INDUSTRIES

J.M. Davies, Inst. of Cancer Research, Division of Epidemiology, *Clifton Ave., Sutton SM2 5PX, England, United Kingdom* (D-IARC-79-699)

A number of towns have been selected, most of which are important centers for industries suspected of giving rise to a bladder cancer risk. As a first step male and female bladder cancer mortality rates in these towns over some 25 years will be compared with national and regional rates. As a second step a total of some 3,000 death certificates of male residents dying with bladder cancer ('cases') will be matched with 'control' death certificates of male residents dying from other causes at the same ages and dates; the occupations of cases and controls will be compared, using the occupations recorded on the death certificates.

2.1961,

TRIAL OF EARLY DETECTION OF BREAST CANCER

J. Chamberlain, Inst. of Cancer Research, Division of Epidemiology, *Clifton Ave., Sutton SM2 5PX, England, United Kingdom* (D-IARC-79-697)

This is an observational trial which aims to determine the effectiveness of alternative early detection programs in reducing mortality from breast cancer. Two populations of approximately 25,000 women aged 45-64 will be offered screening by clinical examination and mammography, two further populations of the same size and age distribution will be offered intensive education in breast self-examination, and at least four additional similar populations, serving as comparisons, will be offered no additional detection services over and above what is normally provided as good current practice. The field-work of the trial will continue for eight years and mortality from breast cancer will be measured in all populations for at least ten years.

2.1962,

EVALUATION OF OCCUPATIONAL HAZARD MONITORING SYSTEMS

J. Bell, Inst. of Cancer Research, Division of Epidemiology, *Clifton Ave., Sutton SM2 5PX, England, United Kingdom* (D-IARC-79-696)

The establishment of information systems for monitoring health of employees (particularly in the oil and chemical industries and those using their products) is under consideration and, in some cases, implementation. However, it is not clear a priori what data must be collected and how they should be analyzed to highlight hazards. Computer simulation of an industrial hazard monitoring system is proposed to answer these questions and to evaluate the potential usefulness of the various systems that have been suggested.

ASBESTOS LUNG AND MESOTHELIOMA SURVEY IN THE UNITED KINGDOM

J.C. Wagner, Medical Research Council, Pneumoconiosis Unit, Dept. of Pathology, *c/o Llandough Hospital, Penarth CF6 1XW, Wales, United Kingdom* (D-IARC-79-684)

The aims of this program are to: (1) determine the number of patients dying in 1976 from primary pleural or peritoneal mesothelioma in the United Kingdom, (2) obtain samples of tumor from each autopsy to confirm the diagnosis and determine histological types, (3) examine lung tissue from each autopsy in order to estimate whether asbestos is present and, if present, the amount and type(s), (4) examine control material for the presence of asbestos comprising (a) tumor and lung tissue from the next case of bronchial carcinoma to come to post mortem, of the same sex and within five years of age of the mesothelioma patient(s) and (b) lung tissue from the next case of cerebrovascular accident to come to post mortem, of the same sex and within five years of age of the mesothelioma patient(s), in 1977 samples of lung alleged to be associated with asbestos exposure, from surgical cases of lung cancer and from post mortem cases with pleural plaques seen at two centers.

FOLLOW-UP STUDY OF WOMEN EXPOSED TO DIETHYLSTILBOESTROL IN PREGNANCY AND THEIR OFFSPRING

M.P. Vessey, University of Oxford, Dept. of Social & Community Medicine, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom* (D-IARC-79-678)

In the early 1950s, a randomized double-blind controlled trial of the prophylactic use of stilboestrol in pregnancy was conducted at a London teaching hospital. The study involved over 1,000 primigravidae and the treatment group received stilboestrol according to the Smith and Smith regimen. The participants in the study and their offspring are now being identified and traced, and death certificates are being obtained for those who have died. Information about the health of survivors will be sought from general practitioners.

RECORD LINKAGE FOR DRUG MONITORING

D.C. Skegg, University of Oxford, Dept. of the Regius Professor of Medicine, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom* (D-IARC-79-676)

There is an urgent need for improved methods of detecting unwanted effects of medicines, especially

delayed effects such as the induction of cancer. A study is being carried out to assess the feasibility of using record linkage for monitoring drugs prescribed by general practitioners. It is hoped to develop methods which could be used in people, all prescriptions dispensed during a two-year period have been linked with records of hospital admissions and deaths (in or out of hospital). For another population of 9,000 people, prescriptions have been linked with records of illnesses seen by the general practitioners. In both cases, the data are being analyzed to identify associations between drugs and diagnoses. A full-scale record linkage scheme would need to cover a larger population and to continue indefinitely; it would be especially suitable for detection of carcinogenic effects of drugs.

MORTALITY IN CHRYSOTILE ASBESTOS TEXTILE WORKERS - IMPLICATIONS FOR HYGIENE STANDARDS

J. Peto, Imperial Cancer Research Fund, Cancer Epidemiology Unit, *9 Keble Rd., Oxford OX1 3QG, England, United Kingdom*

The eventual risk of developing mesothelioma, lung cancer or asbestosis at the current asbestos hygiene standard (2 fiber/ml in the UK) is not known. Dust levels were rarely measured more than 20 years ago, and more recent exposure has not yet caused a detectable excess of cancer. Dust measurements have been made routinely in this factory since 1951, however, and levels from 1933 to 1950 have been estimated. The principal objective is the study of dose and time relationships for mesothelioma and lung cancer, so that the eventual effects of low asbestos exposure can be predicted from the observed effects of relatively high exposures. 1,100 workers exposed for 10 or more years are being followed up through factory and national records. In addition, mesotheliomas in 25,000 previous and current employees are being traced by matching employment records with the UK National Mesothelioma Register to relate incidence to level of exposure and period and duration of employment. Employment records of mesothelioma cases and matched controls will be compared to assess the risks associated with particular processes in the factory.

LUNG CANCER MORTALITY IN A POPULATION EXPOSED TO CHROMIUM DUST POLLUTION

G. Axelsson, Goteborgs Universitet, Dept. of Environmental Hygiene, *411 Vasaparken, S40010 Goteborg, Sweden* (D-IARC-79-501)

The population in a community in Sweden is exposed to air pollution which, to a significant degree, originates from a ferro-chromium industry. The total amount of chromium in the air is 50-200 times higher than background values elsewhere. Death rates in 1961-1975 in the exposed parishes will be compared to those in areas of the same size without chromium emission.

2.1970,

AFLATOXIN AND LIVER CANCER IN SWAZILAND

F.G. Peers, Malkerns Research Station, *P.O. Box 4, Malkerns, Swaziland* (D-IARC-79-500)

Prior studies in Swaziland in 1971 and 1972 established a correlation between liver cancer and dietary aflatoxins, the exposure and disease incidence varying in four topographical areas (Peers et al., Int. J. Cancer, 17, 167-176, 1976). Since then, extensive efforts have been made by the Grain Storage Unit of the Swaziland Ministry of Agriculture to improve 'on farm' storage and in particular to prevent rodent and insect damage. Studies will be made to evaluate how much this improved storage has affected the fungal contamination of dietary staples and hence the dietary aflatoxin exposure and whether this is likely to have a significant effect on the liver cancer incidence. Additional studies will be made to determine the primary sources of the aflatoxin in whole diets, and whether intensive efforts at controlling fungal contamination of dietary staples can be economically effected. Studies will also be made of likely confounding factors, and whether aflatoxins in body fluids can be used as a more direct epidemiological assessment of exposure.

INVESTIGATION OF MORTALITY AND MORBIDITY PATTERNS IN CADMIUM WORKERS IN THE UNITED KINGDOM

G. Kazantzis, Central Middlesex Hospital, Dept. of Community Medicine, *Acton Ln., Horace Soules Hall, London NW10 7NS, England, United Kingdom* (D-IARC-79-630)

Cadmium is a metal carcinogenic in animal experimental studies. Limited observations in man suggest that there may be an increased mortality from cancer of the prostate and of the lung in cadmium workers. The study will, in the first instance, seek to ascertain causes of death in cadmium workers, with particular reference to malignant disease and renal pathology. All persons who have worked with regular exposure to cadmium for a minimum period of one year in selected industries will be included in the study. A retrospective register of cadmium workers from records held by the respective companies will be compiled, and mortality data on this defined population obtained and compared with that of an appropriately matched control group.

LONG TERM SURVEILLANCE OF MORTALITY AND CANCER INCIDENCE IN WOMEN RECEIVING HORMONE REPLACEMENT THERAPY (HRT)

S.A. Adam, University of Oxford, Dept. of Social & Community Medicine, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom* (D-IARC-79-664)

In the proposed investigation women seen at 20 menopause clinics in different parts of the country who (1) are currently using HRT and have been using it continuously for at least one year, or (2) are no longer using HRT, but used it in the past for six months or less, will be recruited and followed up indefinitely using the facilities of the National Health Service Registries. Mortality rates and cancer incidence rates experiences by the short-term and long-term users of HRT will be computed from time to time and comparisons will be made with national mortality and cancer incidence data. Cancer of the endometrium and cancer of the breast are sites of particular interest, as well as cardiovascular disease. It is hoped to recruit around 10,000 women over the next three years.

ETIOLOGICAL FACTORS IN MALIGNANT MELANOMA OF THE SKIN

S.A. Adam, University of Oxford, Dept. of Social & Community Medicine, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom* (D-IARC-79-665)

A case-control study is being conducted to investigate the role of light, genetic factors, and certain drugs, including oral contraceptives, in the etiology of melanoma of the skin. Cases among women under 50 years of age are to be identified through cancer registries, hospital discharge records, and death certificates. The general practitioner of the case will be interviewed and three controls, matched for age, sex, and marital status, will be selected from his records. All cases and controls will be sent a postal questionnaire.

STUDY OF THE RELATIONSHIP IN INDIVIDUALS BETWEEN CERTAIN CANCERS AND OTHER DISEASES

J.A. Baldwin, University of Oxford, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom* (D-IARC-79-666)

The files of linked medical records of the Oxford Record Linkage Study, covering an 8-year period, are being analyzed to ascertain whether persons with certain cancers are at increased risk of having or having had other diseases or disorders. Expected numbers are computed after standardization for variables such as age, sex, period at risk, variation with time and migration out of the area. It is hoped that the study will be able both to identify events or long-standing diseases which might be associated with subsequent malignancy and to ascertain conditions which by their association with the cancer might be considered as having a common etiology with the cancer.

EPIDEMIOLOGY OF PRECANCEROUS AND EARLY NEOPLASTIC LESIONS OF THE UTERINE CERVIX AND CORPUS

S. Munteanu, Institutul Oncologic Cluj-Napoca, Dept. of Early Diagnosis of Uterine Cancer, *34-36 Republicii, 3400 Cluj-Napoca, Romania* (D-IARC-79-472)

The objective is to examine the relations between age at first sexual intercourse, age at first birth, marital status, number of births before age 19 and other known aetiological and epidemiological factors and cervical and corpus neoplasia. A form containing 38 groups of questions, all coded, is filled in by any patient attending the Colposcopy Early Diagnosis Clinic, an out-patient clinic in the Oncological Institute. The following investigative methods are used: Physical examination, various cytological and biopsy examinations, colposcopy, and a thorough inquiry into sexual activity: these are repeated periodically. About 2,500 patients with various benign and malignant cervical lesions and 300 patients with endometrial carcinoma have been recorded and are involved in a long-term follow-up study.

CANCER OF THE OESOPHAGUS

D.G. Hamilton, South African Inst. for Medical Research, Dept. of Morbid Anatomy & Histopathology, *Hospital St., P.O. Box 1038, Johannesburg 2000, Transvaal, South Africa*

Cancer of the oesophagus is one of the commonest tumors in African Blacks but it is infrequent in Whites. Recent work indicates that there may be a difference in tissue trace elements between these two population groups and this might affect serum antioxidant activity. The study aims to quantitate trace elements in White and Black patients by analysis of serum, hair and tissues. Trace elements of particular interest are zinc, iron and calcium. A special subgroup of the Black patients are those with cancer of the oesophagus. Atomic absorption spectrophotometry and neutron activation analysis are being used for trace element studies. A technique measuring the ability of serum to inhibit oxidation in brain tissue assesses its antioxidant activity. Possible further developments of this study will be the effects of dietary modification on tissue trece elements and serum antioxidant activity.

OCCUPATIONAL CANCER RISK ESTIMATION IN CHEMICAL INDUSTRY

B. Barhad, Academia de Stiinte Medicale, Inst. of Hygiene & Public Health, Dept. of Occupational Medicine, *Strada Biserica Amzei 29, Bucharest, Romania* (D-IARC-79-464)

A survey to establish the number of workers exposed to carcinogenic chemicals has been carried out in several large plants in the chemical industry. The data have been correlated with levels and lengths of exposure and cancer morbidity. The study aims to develop better methods of circulating information about workers exposed to carcinogenic substances, taking into account movement of the worker population, retirement and the expansion of the chemical industry, and to apply primary and secondary preventive measures to exposed individuals.

LUNG CANCER MORBIDITY IN WORKERS EXPOSED TO INDUSTRIAL CHEMICALS

R. Maties, Academia de Stiinte Medicale, Inst. of Hygiene & Public Health, Dept. of Occupational Medicine, *Strada Biserica Amzei 29, Bucharest, Romania* (D-IARC-79-466)

The aim of the study is to evaluate the relation between lung cancer and occupational exposure to chromium salts and asbestos. Parameters of exposure which may have an influence on morbidity levels are identified and the relation of possible risk factors other than occupation (smoking habits, residence, previous morbidity) to lung cancer morbidity examined. The project consists of a retrospective study on lung cancer morbidity and mortality among workers exposed to asbestos and bichromates in two plants which have been in operation for more than 30 years, and a prospective follow-up of workers actually exposed. The results of periodical screening (standard chest radiographs, sputum cytology, clinical examination) are recorded and offer a comprehensive description of the changes in the health status.

PRIMARY LUNG CANCER INCIDENCE IN A HIGH RISK GROUP IN AN INDUSTRIAL POPULATION

R. Krzysko, Regional Lung Diseases Control Centre, Unit of Operational Research, *Szamarzewskiego 62, 60569 Poznan, Poland* (D-IARC-79-456)

On the basis of current concepts of a group at high risk for lung cancer, a population suitable for study has been selected. Within this group personal history data are collected and routine cytology and mass miniature radiography (MMR) examinations performed every four months. An estimated 40,000 persons will be available for study, and the cohorts will be followed up for the next five years. There will be a control group consisting of 50,000 persons who have a routine yearly MMR examination. All the data will be finally analyzed in the Unit. Occupational hazards will be simultaneously analyzed by the Environmental Health Unit. It is hoped that epidemiologically significant factors, which may point to a more precise definition of the concept 'at high risk' for lung cancer, will be determined.

2.1992,

THYROID CANCER IN AN ENDEMIC GOITER ZONE

P.A. Rolon, Registro Nacional de Patologia Tumoral, Dept. of Pathology, *G. Arias y Tte. Rodi, Asuncion, Paraguay* (D-IARC-79-446)

The Republic of Paraguay is a region of iodine-deficiency endemic goiter, the frequency being some 30-40% in adults with foci where the disease is even more common. Iodinization of salt began recently. The objective of this study is to determine the incidence of thyroid cancer for the period 1960-1969 and to evaluate the effect of salt iodinization. It is known that the incidence of goiter is decreasing; similar decrease has been observed in Switzerland and Mendoza Province in Argentina. It is hoped that the study of thyroid nodules in a zone of endemic goiter may demonstrate whether there is a direct relationship between goiter and carcinoma. A preliminary study showed a high frequency of anaplastic tumors in Paraguay compared with the Province of Mendoza, possibly due to a failure to differentiate the papillary and follicular forms resulting from lack of iodine.

2.1993,

MALIGNANT TUMORS IN A NATIVE POPULATION UNDER MEDICAL SURVEILLANCE

P.A. Rolon, Registro Nacional de Patologia Tumoral, Dept. of Pathology, *G. Arias y Tte. Rodi, Asuncion, Paraguay* (D-IARC-79-448)

The relationship between cultural factors, social habits and cancer is being studied in a primitive ethnic group of 10,000 persons under the care of a qualified medical doctor. This population is stable and utilizes hospital service provided by the Mennonite settlers in the Paraguayan Chaco. Relative frequency data for cancer for each five-year age-group will determined. The information available consists of clinical and laboratory records as well as histopathological diagnosis. The frequency of cancer will be compared with the habits of this population and with data available in the National Registry of Tumour Pathology. It is realized that results could be biased by excess of easily accessible lesions. However, the regular surveillance and the possibility of examining deep-seated organs should reduce such bias.

2.1994,

MALIGNANT MELANOMA AND GEOGRAPHICAL SITUATION

P.A. Rolon, Registro Nacional de Patologia Tumoral, Dept. of Pathology, *G. Arias y Tte. Rodi, Asuncion, Paraguay* (D-IARC-79-447)

The geographical location of the Republic of Paraguay, in the same latitude as South Africa and Australia, permits study of the anatomical localization of malignant melanoma and the relative importance of cultural and racial characteristics. The Tumour Pathology Registry of Paraguay and the Institute of Pathological Anatomy centralize all histologically diagnosed cancers in the country. Previous study of this material concentrated on the frequency of localizing on the sole of the foot, as the habit of walking barefoot is frequent among the rural population. Cases and clinical details from 1960 are in the Institute files and the period 1976-1980 is now being studied.

CERVICAL CANCER EPIDEMIOLOGY IN PANAMA

W.C. Reeves, Gorgas Memorial Lab. of Tropical & Preventive Medicine, Dept. of Virolog/Epidemiology, *P.O. Box 2016, Balboa Heights, Canal Zone* (D-IARC-79-444)

Uterine cervical cancer rates have been increasing in many developing countries. This is particularly marked in the Republic of Panama, which has the highest reported cervical cancer incidence in the world (130/100,000 per year). In addition to his high overall risk, cervical cancer clusters in one province and invasive disease involves an unusually young age cohort. This study aims to identify and evaluate the risk factors associated with the disease in Panama. All hospital and clinic charts from cervical cancer cases verified histologically in Panama between 1974-1977 are being reviewed and key epidemiological information and clinical data are abstracted onto a standardized cancer registry form. This information will be used to define and describe the marked geographical clustering consistently observed in Panama. Results from this initial analysis may be used to augment or modify a case-control study to be conducted in Herrera Province. The case-control study will collect detailed epidemiological information and sera from all surviving cervical cancer cases diagnosed between 1947-1977 and neighborhood/age matched controls. The information will be gathered and used to test the association of past herpes group virus infection, prior sexual practices, patient drug exposure (including in utero), geographical and other factors with the occurrence of cervical cancer.

2.1996,

POPULATION-BASED PANAMANIAN NATIONAL CANCER REGISTRY

W.C. Reeves, Gorgas Memorial Lab. of Tropical & Preventive Medicine, Dept. of Virology/Epidemiology, *P.O. Box 2016, Balboa Heights, Canal Zone* (D-IARC-79-445)

Cancer has been recognized as one of the three principal causes of death in Panama since 1968. In recognition of this, Panama initiated National Cancer Registry in 1974. This existing registry records all histologically diagnosed cancers in the Republic by annually reviewing all tissue diagnoses from medical facilities which operate pathology services. The registry includes only minimal clinical/epidemiological information which is recorded on index cards. This study intends to convert the current National Cancer Registry into an internationally standardized format and to maintain the registry on a computer system. Hospital and/or clinic charts from all patients with diagnosed cancer between 1973-1977 are currently being reviewed, abstracted and put into the standardized format. Clinical data obtained from charts of patients diagnosed after 1977 will be recorded immediately in the registry. The standardized registry includes all the information recommended in the WHO Handbook for Standardized Cancer Registry as core data, most of the information recommended as optional data, and additional locally important information. Information from registry forms is punched on cards for computer-based storage and data processing. The computer system currently in operation is the Conversational Computer Statistical System developed at the University of Washington, Seattle. Such conversation will allow a detailed epidemiological description of cancer incidence throughout the Republic of Panama. It is specifically intended to investigate the aetiology of uterine cervical cancer, which has an inordinately high incidence in Panama.

2.1997,

INCIDENCE OF PRIMARY CARCINOMA OF THE LIVER IN METROPOLITAN MANILA

J. Baltazar, University of the Philippines, Inst. of Public Health, Dept. of Epidemiology & Biostatistics, *625 Pedro Gil St., Ermita, Manila, Philippines* (D-IARC-79-449)

The marked international variation of the incidence of primary liver cancer probably indicates environmental differences in the population-at-risk. In the Philippines, although autopsy studies had suggested a higher frequency of liver cancer compared to other tumors, incidence data are not available. This population-based study aims to describe the incidence pattern of the disease in a metropolitan area where medical facilities are adequate. From the records of the Central Tumor Registry of the Philippines and from death certificates primary liver cancer cases which were diagnosed during a two-year period, 1975-1976, and which were residents of the study area will be identified. The minimum criterion for diagnosis is clinical evidence of the disease. Overall disease rates as well as those specific for age, sex and administrative subdivisions within the study area will be estimated.

NASAL CARCINOMA IN NICKEL WORKERS

W. Torjussen, Central County Hospital Vest Agder, Dept. of Otolaryngology, *4601 Kristiansand, Norway* (D-IARC-79-441)

The objective of the investigation is to study the influence of occupational nickel exposure on the nasal mucosa and body fluids. Plasma, urine and standardized biopsy specimens from the nasal mucosa from 318 nickel workers, 15 retired nickel workers and 57 controls were analyzed for nickel by atomic absorption spectrometry. The biopsy specimens were also graded histologically to reveal precancerous and cancerous changes by applying light and electron microscopical examinations. Histochemical methods were applied to localize the metal within the tissue. A clinical evaluation by rhinoscopy was used to grade the macroscopic changes of the nasal mucosa. Smoking habits and amounts smoked, duration of nickel exposure, type and amounts of airborne nickel exposure and age were evaluated. Multiple regression analysis was performed to explain the histopathological changes and the rhinoscopical findings by independent variables such as nickel exposure, smoking habits, concentrations of nickel in plasma, urine and nasal mucosa, working categories and age.

2.1999,

FREQUENCY OF PRIMARY LIVER CELL CANCER (PLCC) IN A VILLAGE POPULATION IN RELATION TO CARRIAGE OF HEPATITIS B VIRUS (HBV) AND ITS MARKERS

Y.M. Fakunle, Ahmadu Bello University, University Hospital, Dept. of Medicine, *Zaria, Nigeria*

The aim of this study is to determine the frequency of hepatitis virus and PLCC in a population. It is assumed that other environmental factors, mycotoxins, etc., will exert a similar influence on the population. Individuals with and without markers of HBV will be followed over a long period to detect the development of PLCC. It is hoped that the study will throw light on the role of HBV in the causation of PLCC.

ANALYSIS OF NORWEGIAN DIETARY SURVEY DATA

E. Bjelke, Universitet i Bergen, Inst. of Hygiene & Social Medicine, *5016 Bergen, Norway* (D-IARC-79-440)

The aim of the study is to examine data on diet, alcohol intake, chewing of tobacco or use of snuff, and data on height and weight to assess the relationships of these factors to subsequent cancer incidence and mortality. Data obtained on other variables, such as place of residence, smoking and physical activity will be considered in the analysis. In this on-going prospective study in Norway, about 1,000 new cancer cases among men are now available for diet-cancer analyses. About 1,000 additional cancer cases in females are available for the height/weight analyses. These analyses are part of a larger project, encompassing case-control studies on diet and gastrointestinal cancer carried out previously, other analyses of the prospective study data, and a parellel prospective study in the USA.

NORTHERN BREAST GROUP - BREAST CANCER SURVEY

R. Kay, Auckland University, School of Medicine, Dept. of Surgery, *P.O. Box 2175, Auckland, New Zealand* (D-IARC-79-424)

The purpose of the study is to study the epidemiology of breast cancer in a multi-racial society in New Zealand. This comparison of case characteristics is both between races and within a race. The controls for the latter are 1,000 women attending general practices in Auckland, New Zealand. They will be matched by age and locality with the breast cancer cases. An average of 280 new cases of breast cancer per annum occur in Auckland. Importance is attached to socio-economic groups, height-weight ratios, diet, parity, history of contraceptive practices and previous breast disease. High risk families in Caucasian and Polynesian communities are under review.

POPULATION SCREENING FOR CERVICAL CANCER

P.G. Vooijs, Katholieke Universiteit Nijmegen, Lab. of Cytopathology, Dept. of Pathology, *Geert Grooteplein Zuid 24, Nijmegen, Netherlands*

Cytological screening of the uterine cervix has proved to be a reliable method for detection of early cervical cancer. The degree of acceptance and effectiveness of such a screening program in the Dutch female population is still unknown. To investigate this question, 3 test regions have been created in the Netherlands. One of these is the region around the city of Nijmegen, where women in the age group of 35-54 years are screened every 3 years. The first screening, examining a total of 72,500 women, was done between 1976 and 1979. A second 3 year period will start in August 1979. The accuracy of cytodiagnosis, acceptance of the screening test by the female population, reasons for non-participation and efficacy of organizational procedures are examined. In a long-term follow-up the effects on morbidity and mortality will be calculated. In the whole area (300,000 inhabitants) cervical cancer morbidity is registered.

ESOPHAGUS CANCER IN KENYA

A. Wasunna, University of Nairobi, Dept. of Surgery, *P.O. Box 30197, Nairobi, Kenya* (D-IARC-79-403)

This is a study of case characteristics of carcinoma of the esophagus in Kenya. It is a collaborative project including the Department of Surgery and Pathology, University of Nairobi. Data are collected from all patients with esophageal cancer in Kenyatta National Hospital, Nairobi, and in the provincial hospitals of Kisumu, Western Kenya, and Nyeri in the Central Kenya, where the disease appears to be especially frequent. Questionnaires are administered to all histologically confirmed cases. A standard protocol suitable for computer analysis is being used in the study. In the last 12 months 47 new cases of the disease have been documented at the Kenyatta National Hospital alone. There is now clinical follow-up data on 500 patients at the Kenyatta National Hospital.

RELATION BETWEEN AIR POLLUTION AND CANCER

J. Meilof, National Inst. of Public Health, Epidemiology & Regional Laboratories Division, *P.O. Box 1, Antonie Van Leeuwenhoeklaan 9, 3720 BA Bilthoven, Netherlands* (D-IARC-79-411)

In this collaborative project of the International Agency for Research on Cancer and the National Institute for Public Health (RIV) correlation study of air pollution and cancer will be developed which will exploit the unique automated system of air pollution monitoring existing in the Netherlands. The pollution data collected are such that it is possible to produce an integrated average exposure to sulphur dioxide, the oxides of nitrogen, ozone and carbon monoxide for a large number of areas covering the entire country. The Netherlands National Vital Statistics Office will be consulted for information on cancer and other death rates for the areas considered to be meaningful for atmospheric pollution exposures. The Automated Pathological Diagnoses Storage and Retrieval System (PALGA) has an important potential for epidemiological studies as the information about cases of cancer is based on histological diagnoses.

NUTRITION AND CANCER OF THE COLON - A CASE-CONTROL STUDY IN SPECIFIC GEOGRAPHIC REGIONS OF THE NETHERLANDS

P.F. Guchteneire, Inst. of Social Oncology, *Dr. Molewaterplein 50, Postbus 1738, 3000 DR Rotterdam, Netherlands* (D-IARC-79-417)

Mortality rates for cancer of the colon have been increasing in the Netherlands, as in most Western countries. The standardized mortality rates for colon cancer have been reviewed for the different regions of Holland, and an excess mortality was found in the southern part of the country as compared to the northern part. Dietary differences between the northern and southern provinces could in part be responsible for this variation. A study has been designed to investigate in selected geographic regions the role of nutrition in the causation of cancer of the colon. Nutrient intake data from newly diagnosed colon cancer patients obtained by means of a dietary history questionnaire will be compared to that obtained from hospital and population controls. The effect of socio-economic factors on dietary habits is taken into consideration. Microbiological and biochemical investigations are being considered. A pilot study has been completed.

PRENATAL EVENTS AND CANCER RISK IN THE OFFSPRING

D. Dukkers van Emden, Universiteit van Amsterdam, Dept. of Neonatology, *Spui 21, Amsterdam, Netherlands* (D-IARC-79-410)

The objective is to examine the relationship between use of anti-epileptic drugs or viral infection during pregnancy and cancer risk in the offspring. A follow-up study has been done of the outcome of 249 pregnancies in epileptic women undergoing treatment with anticonvulsants. The children were born 1963-1977. Three children were stillborn, none died subsequently. Postmortem examination in six cases showed multiple congenital abnormalities, no signs of malignancy. In the remaining group of 237 children, one boy, born in 1966, developed Hodgkin's disease (stage I) in 1973. His mother had used phenytoin, phenobarbital and primidone in high dosages during the entire pregnancy. No other malignancies were found in the group. A follow-up study is being done of a small group of children born 1974-1976, with posible congenital infection. So far one possible case of congenital leukemia has been found in a child with possible congenital cytomegaly infection. No other malignancies have been found in the group to date.

EPIDEMIOLOGY OF NASOPHARYNGEAL CARCINOMA IN JAPAN

S. Sawaki, Yokohama City University, School of Medicine, Dept. of Otorhinolaryngology, *3-46 Urafune, Minami-Ku, Yokohama 232, Kanagawa Ken, Japan* (D-IARC-79-401)

The incidence of nasopharyngeal carcinoma is highest in the populations of Southern China, while in Japanese it is very low. This descriptive epidemiological study of nasopharyngeal carcinoma in Japan aims to discover the reason for this difference. The nasopharyngeal carcinoma cases, observed in the major hospitals of the whole of Japan are reported to this laboratory each year. Age and sex distributions, geographical variation and ethnic background will be examined. Histological sub-classifications of the reported cases are being made, and relationships to Epstein-Barr virus infection (anti-VCA-anti-body titers, etc.) examined.

CASE-CONTROL STUDY OF ESOPHAGEAL CANCER

K. Aoki, Nagoya University, School of Medicine, Dept. of Preventive Medicine, *65 Tsurumai-cho, Showa-ku, Nagoya 466, Aichi ken, Japan* (D-IARC-79-361)

A high incidence of deaths from esophageal cancer has been recorded in Wakayama Prefecture, where some dietary factors are suspected as carcinogenic agents. Aichi Prefecture has had a low death rate for the same three decades. The purpose of this case-control study is to clarify the role of dietary factors such as hot tea gruel, bracken-fern and others, and also of socio-economic factors in esophageal cancer. The differences between epidemiological features of the esophageal cancer patients in Wakayama and Aichi are to be compared. One hundred fifty cases of esophageal cancer and 300 controls in

Aichi and 100 cases and 200 controls in Wakayama are to be interviewed. Cases are the patients admitted into major hospitals in Nagoya and Wakayama cities. Controls are selected from all patients admitted to the same hospitals, matching age, sex, residence, and date of admission, excluding patients with cancer.

GEOGRAPHICAL VARIATIONS AND TIME TRENDS OF CANCER MORTALITY IN JAPAN

T. Kuroishi, Aichi Cancer Center Research Inst., Division of Epidemiology, *81 1159 Kanokoden Tashiro-cho, Chikusa-ku, Nagoya 464, Aichi, Japan* (D-IARC-79-365)

Mortality from some malignant neoplasms in Japan shows marked variations in geographical distribution and secular trends. This study aims to describe mortality from cancers of 18 sites for each prefecture and smaller administrative districts in Japan (1969-1976) and to find possible cancer risk factors by examining geographical and chronological relationships between mortality from cancers of various sites and various environmental factors, such as air pollution, food intake, smoking, socioeconomic factors, etc.

2.2016,

ANALYSES OF GEOGRAPHICAL VARIATIONS AND TIME TRENDS OF MORTALITY FROM MALIGNANT LYMPHOMAS IN JAPAN

H. Shimizu, Aichi Cancer Center Research Inst., Division of Epidemiology, *81 1159 Kanokoden Tashiro-cho, Chikusa-ku, Nagoya 464, Aichi, Japan* (D-IARC-79-371)

The aim of this study is to discover aetiological factors in malignant lymphoma. As a first stage the geographical distribution of mortality from reticulum-cell sarcoma, lymphosarcoma, Hodgkin's disease and other neoplasms of the lymphoid tissue was generally high in the south-western parts of Japan for both sexes in 1969-1976. The geographical distribution of malignant lymphoma was similar to that of lymphatic leukemia in the same period in Japan. The mortality rate of Hodgkin's disease has been calculated for each city and town in two prefectures with a high mortality and several clusters were found in districts around a bay or in small islands in southern parts of Japan. It is considered that these malignancies of the lymphatic and hematopoietic tissue might be caused by similar agents. Pathological information has been collected from Japan Autopsy Reports and this will be analyzed to explore causal factors of the disease. It is also planned to collect and analyze the medical records of malignant lymphoma patients in the Aichi Cancer Center Hospital.

LUNG CANCER MORTALITY AND AUTOMOBILE EMISSIONS

H. Shimizu, Aichi Cancer Center Research Inst., Division of Epidemiology, *81 1159 Kanokoden Tashiro-cho, Chikusa-ku, Nagoya 464, Aichi, Japan* (D-IARC-79-370)

To examine the causal association between exposure to vehicular emission and lung cancer, the mortality rates for lung cancer (1969-1974) were analyzed among inhabitants living in the areas within 100 meters from main streets on which more than 1,000 cars pass daily from a.m. to 7 p.m. in Nagoya City. Traffic volume was used as an indicator of the degree of exposure to exhaust gas. The preliminary results show an increase in the standardized mortality ratio (SMR) of lung cancer in parallel with the traffic volume for males. However, for females the SMR was highest in the intermediate areas and did not parallel the traffic volume. No apparent relationships were observed between proximity to streets and lung cancer mortality. Mortality adjusted by smoking history, history of hazardous exposure and residential history showed similar results. The study continues.

RELATIONSHIP BETWEEN AIR POLLUTION AND CANCER IN JAPAN

S. Tominaga, Aichi Cancer Center Research Inst., Division of Epidemiology, *81 1159 Kanokoden Tashiro-cho, Chikusa-ku, Nagoya 464, Aichi, Japan* (D-IARC-79-373)

This study aims to clarify the relationship between air pollution and cancer mortality. Sulphur dioxide (SO_2) and nitrogen oxide (NO_2) levels and dust fall were used as indices of air pollution. The average value of each pollutant for each of the 46 prefectures (1967-1975) was related to the age-adjusted mortality rates of cancers of the lung, oesophagus, stomach, breast and uterus (1975) for the corresponding prefecture. In examining relationships between air pollution and cancer mortality, smoking was also taken into account. The relationship between SO_2 and lung cancer and breast cancer in females and that between NO_2 and lung cancer in both sexes and breast cancer in females was statistically significant after taking into account the proportion of smokers.

THE LATE RADIATION EFFECTS OF ATOMIC BOMB EXPOSURE IN THE POPULATION OF HIROSHIMA AND NAGASAKI, JAPAN

M. Tamaki, Radiation Effects Research Foundation, *5-2 Hijiyama Pk., Hiroshima 730, Hiroshima, Japan* (D-IARC-79-346)

The Atomic Bomb Casualty Commission (ABCC) in Japan was organized in 1947 under the supervision of the U.S. National Academy of Sciences (NAS) to detect late radiation effects in the people of Hiroshima and Nagasaki exposed to the 1945 atomic bombs. In 1975 ABCC was reorganized as the Radiation Effects Research Foundation (RERF), a private non-profit foundation funded equally by Japan and the United States. The RERF offices, laboratories, and examination facilities are maintained in both Hiroshima and Nagasaki, where adult health examinations, autopsies, clinical research, and epidemiological studies are conducted. The basic population for the epidemiological and autopsy studies numbers about 70,000 persons. Biennial clinical examinations are conducted on about 15,000 survivors and their controls in the two cities. A number of important radiation-related clinical disorders and abnormalities have been detected in the atomic bomb survivors, including increased frequency of lenticular opacities, thyroid tumors, leukemia, chromosome aberrations in the peripheral lymphocytes, and slight impairment of growth and development of those exposed early in life. Microcephaly and mental retardation have been noted in some of those exposed in utero, especially if significant exposure occurred during the early period of gestation. Recent findings indicate an increased incidence of solid tumors among the more heavily irradiated survivors, most apparent for breast and lung cancers; this may extend to cancer of stomach and other sites. The RERF plans to continue its health examination, mortality, and autopsy programs. Particular attention in the clinical examination population is now being focused on early cancer detection, cancer education, alteration of immunologic competence, and acceleration of aging. The tumor and tissue registry programs in Hiroshima and Nagasaki complement the RERF studies for the detection of radiation-induced tumors.

CANCER OF THE OROPHARYNX - A CASE-CONTROL STUDY

S. Sivayoham, National Cancer Registry, Dept. of Health Services, *385 Deans Rd., Colombo 10, Sri Lanka* (D-IARC-79-497)

The data available from the Sri Lanka National Cancer Registry show that oropharyngeal neoplasms constitute 39% of all cancers in Sri Lanka. The age-adjusted rates, when compared with other cancer registries, are very high, if not the highest. For example, the age-adjusted rate for mouth cancers is 56.7 for males and 20.5 for females, many times higher than that provided by any other registry. The objective of the present epidemiological investigation is to study the association between possible risk factors, betel chewing, smoking, the consumption of alcoholic drinks, oral hygiene, socioeconomic factors, and oropharyngeal cancers in Sri Lanka. The cases will be drawn from the Cancer Institute, Maharagama, and the General Hospital, Colombo, and the control group from non-cancer inpatients of the General Hospital, Colombo.

A PROSPECTIVE SURVEY OF CANCER IN LESOTHO 1970-1974

P.M. Martin, University of Botswana Lesotho & Swaziland, *Swaziland Campus, Kwaluseni, Swaziland* (D-IARC-79-499)

1,223 cases of cancer have been collected between 1970 and 1974. The crude rates and epidemiology of the main cancers (cervix, breast and liver) are being determined with the help of the recently published Lesotho Census of 1976. Analysis of the questionnaires completed by the patients show that they are more traditional, less educated and poorer than a similar group of healthy controls. Furthermore, cancer of the cervix patients ingest substantially more fermented porridges and drinks which have been recently shown to contain the mycotoxin zearalenone.

LEUKEMIA IN SUDAN

M.A. Ahmed, University of Khartoum, *P.O. Box 102, Khartoum, Sudan* (D-IARC-79-498)

Only a few preiminary studies, consisting of small numbers of cases, have been published on the incidence of leukemia in the Sudan. This vast country has unparalleled variations in environment and ethnic backgrounds. The present study aims to assess the incidence of the different types of leukemia by age and sex and their regional distribution within the Sudan and to find out whether there is any association between environmental factors and the incidence of leukemia. A personal history which includes the locality and the patient's tribe is taken for all the leukemia cases seen during the period of the study. These cases are examined by one or more of the study collaborators and clinical diagnosis is made. The latter is confirmed by peripheral blood count and a bone marrow examination which are carried out in the hematology department of the University of Khartoum. Cytochemical staining is used in the controversial cases. The findings are recorded on special cards and at the end of the first part of the study 256 cases have been collected.

COHORT STUDY OF CHROMIUM-EXPOSED WORKERS

R. Puntoni, Universita degli Studi di Genova, Inst. de Oncologia, Dept. of Epidemiology, *Viale Benedetto 15, Pad. B, 16132 Genoa, Italy* (D-IARC-79-321)

In the Liguria region there is a factory that produces both hexavalent and trivalent chromium salts. The workers in the factory are exposed to large doses of chromium. An investigation of the causes of death among about 1,300 workers employed in the period 1 January 1958 to 1 January 1978 is being undertaken. The expected deaths will be calculated on the basis of the death rates for the people living in the two villages surrounding the factory.

COHORT STUDY OF REFINERY WORKERS

R. Puntoni, Universita degli Studi di Genova, Inst. de Oncologia, Dept. of Epidemiology, *Viale Benedetto 15, Pad. B, 16132 Genoa, Italy* (D-IARC-79-322)

In the town of La Spezia there is a big refinery. The workers, approximately 500, at this refinery are exposed to several petroleum derivates. Many of these chemicals are well-known carcinogens, for instance polycyclic hydrocarbons. An investigation into the causes of death of those workers is being carried out and data on all the causes of death in the period 1960 to 1977 compiled. For comparison, the expected number of deaths will be estimated from age-specific male death rates for the La Spezia population during the same period.

2.2032,

MORTALITY EXPERIENCE AMONG POLYCHLORINATED BIPHENYL WORKERS

P.A. Bertazzi, Universita degli Studi di Milano, Inst. of Occupational Health, Dept. of Epidemiology, *Via San Babila 8, 20122 Milan, Italy* (D-IARC-79-324)

Animal experiment studies and some human data support a possible association between polychlorinated biphenyls (PCBs) exposure and cancer in man. The aim of the study is to assess mortality in the period 1955-1975 among workers employed in a capacitor and transformer industry operating since 1947. The personal records of the 2,317 workers employed since the beginning of manufacture have been obtained from the factory. For each subject date and place of birth, date of entry and leaving the industry and type of work performed are available; date, place, and primary cause of death will be ascertained from death certificates. The sex, age and cause-specific mortality of people living in the same city where the factory is located will be used for comparison.

PRIMARY INTRACRANIAL TUMORS IN TRIESTE

C. Bianchi, Universita degli Studi di Trieste, Fac. di Medicina, Inst. of Pathological Anatomy & Histology, *via Stuparich 1, Trieste, Italy* (D-IARC-79-335)

Cases in which a diagnosis of primary intracranial tumor is made at biopsy or autopsy in the Province of Trieste will be collected. Detailed personal and medical data will be obtained for each case from the patient or relatives by personal interview. In this, attention will be focused on the following points: diet, tobacco and alcohol habits, residence at different periods of life, occupational history, contacts with animals, vaccinations, viral diseases, diagnostic and therapeutic radiations, drug use, etc.

A FOLLOW-UP STUDY OF LEPROSY PATIENTS

S. Tokudome, Kyushu University, School of Medicine, Dept. of Public Health, *3-1-1 Maidashi, Higashi-ku, Fukuoka City 812, Fukuoka ken, Japan* (D-IARC-79-343)

It is known that there is a high cell-mediated immune response in tuberculoid leprosy, whereas such a response is absent in lepromatoid leprosy. Recently DDS (diamino-diphenyl-sulfone), which is used to treat leprosy, has been found to be carcinogenic in animal experiments. The aim of this study is to examine the mortality of leprosy patients with special reference to malignant neoplasms. Some 2,000 patients admitted to a leprosarium, from 1956 to 1977, are analyzed by types of the disease and their mortality experience is compared with that of the general population in Japan. The data will also be analyzed in terms of possible carcinogenicity in patients treated with the drug.

EPIDEMIOLOGY OF CHILDHOOD CANCER IN THE PROVINCE OF TORINO, ITALY

G. Pastore, Universita degli Studi di Torino, Istituto di Anatomia e Istologia Patologica, *Via Santena 7, I10126 Turin, Italy* (D-IARC-79-338)

A special registry of cancers in children (ages 0-14) among residents in the Province of Torino (total population at the 1971 census 2,287,016, of which 497,223 were ages 0-14) has been operating since 1965. Possible sources of reports are periodically visited and controlled to ensure that reporting of cancers in children to the Cancer Registry is complete. Data for 1965-1974 have been submitted for publication. Rates are similar to those of other industrialized countries in the Western world. Incidence and mortality rates of cancer at different sites have been calculated for the city of Torino and the rest of the province as well as for different areas within the province. Only neurogenic tumors show some geographical differences. By July 1979 collection of cases will be completed for the period up to December 1978. Trends in incidence, mortality and lethality rates are being investigated as well as the distribution of cancer in children among the autochthonous population as compared to the population immigrating from other parts of Italy.

EPIDEMIOLOGY OF KAPOSI'S SARCOMA IN SARDINIA

D.M. Cerimele, Universita degli Studi di Sassari, Dept. of Dermatology, *Viale Mancini 5, 07100 Sassari, Italy* (D-IARC-79-330)

The main goal of the present research is to analyze the incidence of Kaposi's sarcoma in Sardinia and to establish whether generalized forms of the disease, like those described in Uganda, are present and to what extent. Kaposi's sarcoma in Sardinia does seem to be more frequent than in other parts of Italy and is certainly more frequent than in the other countries of Europe. The study will investigate the distribution of Kaposi's sarcoma in Sardinia to see if the disease is more common on the coast or in the interior part of the island and if the disease is associated with other diseases such as diabetes, malaria, tuberculosis, Mediterranean anemia, Hodgkin's disease or other lymphomas. An examination of cell-mediated immunity in patients affected by Kaposi's sarcoma has been started to investigate whether there is a correlation between the generalization of the disease and a possible impairment of the cell-mediated immunity.

ENVIRONMENTAL FACTORS AND THE DEVELOPMENT OF SKIN CANCER

D.M. Cerimele, Universita degli Studi di Sassari, Dept. of Dermatology, *Viale Mancini 5, 07100 Sassari, Italy* (D-IARC-79-331)

There is ample evidence that environmental factors and particularly prolonged exposure to the rays of the sun play a significant role in the development of skin cancer. This study intends to determine the actual incidence of skin cancers in Sardinia, and the degree to which environmental and constitutional factors are involved. A questionnaire, developed for the present study, collects information from skin cancer patients on place of birth, place of residence during last ten years, place of present residence, color of the skin, eyes and hair, capacity to tan and time of exposure to the sun. Patients treated are followed up in order to establish if people who develop skin cancer are prone to develop new cancers of the skin or inner organs in the future.

SURVIVAL OF BREAST CANCER PATIENTS RELATED TO RISK FACTORS

M.L. Purde, Ministry of Health of the Estonian SSR, Inst. Eksper. i Klin. Medit., Dept. of Clinical Oncology, *42 Hiiu St., Tallinn 200015, Estonian S S R, Union of Soviet Soc. Republics* (D-IARC-79-1085)

Survival rates for patients with breast cancer have been reported to be different not only due to the extent of the disease and efficiency of the treatment but also in connection with some other factors. This research is based on samples from the previously presented case -control study, consisting of 500 breast cancer cases who have undergone initial treatment in the period 1967-1973. The surveillance system is introduced by the Estonian Cancer Registry. The aims of the study are to evaluate the relationship between certain risk factors (family history, age at first birth, age at menarche, some allied diseases) and probability of survival.

AN ASSESSMENT OF ORCEIN-POSITIVE STAINING IN THE LIVERS OF PATIENTS WITH HEPATOCELLULAR CARCINOMA

C. Isaacson, South African Inst. for Medical Research, *Hospital St., P.O. Box 1038, Johannesburg 2000, Transvaal, South Africa* (D-IARC-79-487)

Several studies in Africa have shown that there is a high incidence of HBAg positivity in the non-neoplastic liver in subjects with hepatocellular carcinoma. This is also apparent in several studies from Southern Africa with particular reference to the Shangaan miners working in tha South African gold mines and coming originally from Mozambique. In these, approximately 30-40% of the subjects with hepatocellular carcinoma also show orcein-positive staining for HBAg in the non-neoplastic liver. However, a random study of hepatocellular carcinomas diagnosed at Baragwanath Hospital itself has failed to demonstrate similar findings. It should be pointed out that the population served by Baragwanath Hospital is derived from Soweto, a large urban center twelve miles south west of Johannesburg. The majority of these subjects have, therefore, been in an urbanized situation for some considerable time. A random study of something like 36 hepatocellular carcinomas showed only two with orcein positivity in the non-neoplastic liver. This study should be expanded into a prospective one, because if these findings are confirmed, the importance of the hepatitis B virus in the aetiology of hepatocellular carcinoma must diminish. It is possible that, although these subjects may be HBAg surface antigen-negative, they may turn out to be core antigen-positive.

EPIDEMIOLOGY AND HISTOLOGICAL AND ELECTRON MICROSCOPIC DIAGNOSIS OF THYROID CANCER - IODINE PROPHYLAXIS

F. Hofstadter, Leopold Franzens Universitat Innsbruck, Pathologisches Institut, *Muellerstr. 44, A6020 Innsbruck, Austria*

OBJECTIVE: To study endemic goiter, particularly with regard to systematic iodine prophylaxis by means of iodinizing salt, established in 1960.
APPROACH AND PROGRESS: In the Swiss endemic goiter area an analogous salt prophylaxis was introduced about 30 years ago. In this tumor material some interesting changes in morphology and clinical behavior have been noticed, and the results published.
We revised our histological tumor material from the years 1952-1975 and classified the specimens according to the WHO schedule, using uniform criteria. The exact morphological diagnosis (including number of infiltrations of the tumour capsule and blood vessels) was correlated with the clinical course of the disease. The total number of reclassified carcinomas was 453.
Furthermore we studied the epidemiological criteria of these carcinomas (sex, age, incidence) in contrast

to the 10423 non-malignant thyroid tumors. In order to determine the value of diagnostic improvement influencing the morphological pattern of thyroid tumors, we studied the preoperative clinical findings of the non-malignant thyroid tumors (symptoms, radiology, scintigrams, cytology) and correlated these data with the morphological features (weight, macroscopy, histology). For selected years (before and after the introduction of iodine prophylaxis) we studied the lymphocytic infiltration of the thyroid specimens and found a severe increase in this alteration after iodine prophylaxis. To evaluate this dependency of the morphology and biology of thyroid neoplasms on the specific endocrine situation we studied 25 thyroid carcinomas by means of electron microscopy. In differentiated carcinomas we often found disorganization of cytoplasmic organelles such as hyperplasia or hypertrophia of a single organelle type (mitochondria, lysosomes, rough and smooth ER, cytoplasmic vesicles). These findings will allow us to study the physiologic function of the respective cytoplasmic organelles.

CANCER AMONG RUBBER WORKERS AND ESTIMATION OF CANCER RISK BY URINARY THIOETHER EXCRETION OF WORKERS

I.V. Kilpkari, Tampere Yliopisto, Dept. of Public Health, *Vuolteenkatu 11, 33100 Tampere 10, Finland*

OBJECTIVES: 1. To determine the risk of cancer and risk at mortality among workers at a Finnish rubber factory. 2. Urinary thioether excretion is correlated with exposure under working conditions. 3. Whether urinary thioether excretion is correlated with incidence to cancer among rubber workers.

APPROACH: Epidemiological methods are used to evaluate cancer incidence and mortality by cause of death in groups of workers with different exposure. Urinary thioether excertion is correlated with work conditions and with risk of cancer for purpose of prevention.

2.2050,

OCCUPATIONAL, ATMOSPHERIC AND DIETARY FACTORS AND HABITS ASSOCIATED WITH EPIDERMOID CARCINOMA OF THE BUCCAL CAVITY IN CHILE

O. Inzunza Hernandez, Hospital Jose Joaquin Aguirre, Asignatura de Fisiopatologia, *Av. Santos Dumont 999, Santiago, Chile* (095)

OBJECTIVE: Information is available in the world literature on factors associated with buccal cancer, such as alcohol and tobacco consumption, diet and other habits. Given the ethnic, geographic, cultural and social differences between Chile and the countries producing this information, we propose to study the factors associated with buccal cancer in this country. The final objective is to apply the information obtained to the diagnosis of a population at high risk of developing buccal cancer and to implement in those persons preventive methods and early diagnosis of the neoplasia. We believe that based upon this analysis we will be able to detect mutagens for further study.

METHODS: 1) Analysis of morbidity and mortality statistics for buccal cancer throughout the country, studying the extent of the sample, distribution by anatomic site, distribution by geographic site, etc. 2) Analysis of the type of diagnosis, e.g., clinical, radiographic, histopathologic, type of pathology, degree of extension of the lesion, etc. 3) Using records of various treatment centers, compile a list of patients who are alive, who have epidermoid carcinoma of the buccal cavity or premalignant or potentially cancerous lesions. 4) Selection of a control group, two controls per cancer patient, comprised of individuals with the following similar characteristics: race, age, level of education, place of residence, occupation. 5) Interview of patients and controls to include: time of development of the lesion, prior diseases, teething, family history, occupation, place of residence, diet, habits, etc. 6) Tabulation and discussion of results.

PROGRESS: We have completed steps 1 and 2 and we are currently compiling a list of patients with epidermoid carcinoma of the buccal cavity.

MELANOMA, ITS AETIOLOGY AND EPIDEMIOLOGY, AND THE MECHANISM OF SPONTANEOUS REGRESSION

V.J. McGovern, Royal Prince Alfred Hospital, Fairfax Inst. of Pathology, Dept. of Histopathology, *Missenden Rd., Camperdown, N.S.W. 2050, Australia*

OBJECTIVES: (a) The exact relationship of solar exposure with the development of melanoma. (b) The nature of regression: spontaneous regression occurs chiefly in melanoma with a intra-epidermal component, and it is characterized by a lymphocytic infiltrate. The process may cease before the tumor is completely destroyed, the lymphocytes disappear and fibrosis occurs. The regression process does not affect metastatic melanoma except for metastases in the skin.

APPROACH: (a) The apparent anomalies in the site-incidences in Queensland may be due to wearing transparent clothing. This has to be investigated. (b) To determine which type of lymphocyte is principally involved.

A STUDY OF THE USE OF TOBACCO AND ALCOHOL BY MALES AND FEMALES OF TRANSKEI

J.S. Harington, National Cancer Assn. of South Africa, Cancer Research Unit, *9 Jubilee Rd., Johannesburg 2000, Transvaal, South Africa* (D-IARC-79-484)

Cancer of the oesophagus occurs at very high frequency in Transkei. There is evidence that the use of commerical pipe tobacco smoked either in pipes or as hand-rolled cigarettes may be responsible, or partly responsible, for the disease. To investigate this, a field study of geographical regions having higher and lower incidence rates (than the overall rate) of oesophageal cancer in the resident population of Transkei was carried out. Nine hundred detailed questionnaires are now being analysed and results will shortly be available.

JAPAN-HAWAII CANCER STUDY

A.M. Nomura, Kuakini Medical Center, Dept. of Pathology, *347 N. Kuakini St., Honolulu, Hawaii* 96817 (D-IARC-79-794)

In recent years the Japanese in Hawaii have experienced cancer incidence and mortality rates which are intermediate to the rates of indigenous Japanese and US-Whites. Because genetic variables are presumably held constant in comparisons between native and migrated Japanese, this shift in the cancer experience of the 'Westernized' Japanese in Hawaii strongly suggests that environmental factors play a major role in oncogenesis. Furthermore, this spontaneous sociomedical experience among the Japanese provides a unique opportunity to isolate specific environmental, biochemical and pathologic variables which may be etiologically associated with different types of cancerous lesions. Of special interest is the observed reciprocal relationship of gastric and colorectal cancer among the migrant Hawaii Japanese. They have manifested a falling rate for gastric cancer and a rising trend for malignant colorectal tumors. The study has utilized the examined population of the Honolulu Heart Program, which consisted of 8,006 men of Japanese ancestry who were born from 1900 through 1919 and seen from 1965 to 1968 in Hawaii. Approximately 6,800 of the men have since returned for a repeat examination, and these are the men now under surveillance in the Japan-Hawaii center study. There are three major end points in this surveillance: (1) The occurrence of new cases of cancer; (2) Deaths due to different types of cancer; (3) Appropriate pathologic findings from surgical specimens or necropsies.

EPIDEMIOLOGICAL ANALYSIS OF EFFECTS OF RADIUM

R.E. Rowland, Argonne National Lab., Radiological & Environmental Research Division, *9700 S. Cass Ave., Argonne, Illinois* 60439 (D-IARC-79-799)

Epidemiological studies are being conducted in order to determine the health effects of exposure to radium. Persons exposed to radium in various parts of the United States are being traced from records of radium dial companies and from other sources. Follow-up of persons located includes determination of vital status and analysis of causes of death (obtained from death certificates) for all, and medical examination, measurements of body radioactivity, and analysis of autopsy reports or materials for part of the group. Analyses of morbidity and mortality are made within the group in relation to body burden of radium. Dose-response patterns are being determined for bone sarcomas with reference to bone sarcomas and carcinomas of the mastoids and the paranasal sinuses. Further analyses will involve other diseases. Mortality and morbidity in specific subgroups of radium cases (e.g., radium dial workers ascertained from employment lists) are being compared with U.S. statistics, with consideration of sex, and other demographic characteristics. At present, about 2,000 persons have been located and measured for radioactivity. Studies of the health of the offspring of certain groups (i.e., female radium dial workers) are also planned.

SEARCH FOR AN ETIOLOGICAL AGENT IN HODGKIN'S DISEASE AND RELATED LYMPHOPROLIFERATIVE DISEASES

B.E. Henderson, University of Southern California, School of Medicine, Dept. of Pathology, *2025 Zonal Ave., Los Angeles, California* 90033 (D-IARC-79-723)

There have been several recent reports of familial and non-familial clustering of Hodgkin's disease. The unusual aggregations suggest the possibility that Hodgkin's disease is caused by an environmental agent, possibly a horizontally transmitted virus. Results of HL-A typing indicate that out of a total population, only a subset is susceptible to development of Hodgkin's disease upon exposure to this hypothetical environmental agent. Some of these more susceptible individuals may possibly be found among the members of families with multiple cases of malignant lymphoproliferative diseases. The University of Southern California, school of Medicine, Cancer Research Program is currently involved in trying to identify these most susceptible individuals. In order to follow up the earlier studies of Hodgkin's disease as well as to obtain new information on the other malignant lymphomas, a broad study has been initiated of all malignant lymphoproliferative neoplasms diagnosed during 1972 and 1973 in Los Angeles county. The approximately 2,400 (ALL 180, CLL 24, multiple myeloma 360, Hodgkin's disease 440 and non Hodgkin's lymphomas 1,160) neoplasms expected during this two-year period are being studied in detail. The basis for the histological diagnosis will be reviewed by Dr. Lukes and his co-workers and, as a minimum, the pathological slides on all Hodgkin's and non-Hodgkin's lymphomas during 1972 will be reviewed.

THE RELATIONSHIP OF SOCIOECONOMIC TRENDS TO BREAST CANCER AND FEMALE GENITAL CANCER

M.H. Brenner, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Public Health Administration, *615 N. Wolfe St., Baltimore, Maryland* 21205 (D-IARC-78-659)

Epidemiological studies of the socioeconomic distribution of cancer have tended to show an inverse relationship with socioeconomic status, except for breast cancer. These studies, however, were conducted at specific points in time, rather than concentrating on changes in time trends. The present study determines age-specific trends in mortality due to female breast and female genital cancer (including total female genital cancer, uterine and specifically cervical, and ovary-fallopian tube) for the United States, Great Britain and Sweden during 1921-1968. Breast cancer mortality shows inverse relations to national economic fluctuations for the United States and Britain, but not for Sweden, at lags of 2-6 years, while inverse relations with national economic indicators are seen for cancer of the female genital organs for all three countries at lags of 5-9 years. Among alternative explanations are involvement of endocrine factors and psychophysiological stress.

NATIONAL HUMAN MONITORING PROGRAM FOR PESTICIDES

F.W. Kutz, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Biometry Section, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (D-IARC-79-994)

The National Human Monitoring Program for Pesticides is responsible for determining incidences, levels, and other evidence of pesticide exposure in the general population of the conterminous United States, and for identifying changes and trends. This programme currently comprises two major projects. The older of these consists of the collection and organochlorine pesticide residue analysis of adipose tissue samples collected from residents of cities selected according to a proportionate stratified-random design. For each of these 40 areas an annual quota reflecting age, sex, and race distribution at the most recent national census is defined. Approximately 1,600 human fat specimens are scheduled for collection annually. In addition to the individual results of the multi-residue analysis, data collected for each person sampled include: age, race, sex, geographic location, occupation, height, weight, and diagnoses at the time of sampling. All data are managed electronically, making retrievals of any of the above possible. More recently, in cooperation with the Public Health Service's Health and Nutrition Examination Survey II (HANES II), blood serum and urine are being collected from a sub-sample of 7,500 persons in the general population of 75 cities over a 3-year period to yield baseline data on levels of selected organochlorine insecticides in serum. Urine analysis will provide information on organophosphate and phenoxy herbicides, and other new classes of pesticides. A wide range of epidemiological studies is planned.

HEALTH EFFECTS OF ASBESTOS EXPOSURE IN NAVAL SHIPYARD WORKERS

L.N. Kolonel, University of Hawaii System, Manoa Campus, School of Public Health, Dept. of Biomedical Sciences, *Spalding Hall, Room 255, Honolulu, Hawaii* 96822 (D-IARC-79-787)

A retrospective cohort of 9,000 male shipyard workers employed at the Pearl Harbor Naval Shipyard in 1950, and subsequently through 1968, has been identified. Complete work histories have been obtained for each man, as well as records of environmental levels of asbestos. Follow-up of these men for their vital status as of 1974 is in progress. Mortality from all causes, respiratory diseases, and site-specific cancer will be compared with that expected based on the mortality experience of the Hawaii population of comparable age, sex and race. Smoking histories will be obtained from the living cohort in Hawaii, who will then be followed prospectively for morbidity and mortality over the next several years. The possible synergism between smoking and asbestos exposure in the risk of cancer will also be examined.

EVALUATION OF PERIODIC BREAST CANCER SCREENING BY MAMMOGRAPHY

R. Fink, Health Insurance Plan of Greater New York, Research & Statistics, *625 Madison Ave., New York, New York* 10022 (D-IARC-78-911)

OBJECTIVES: A. To determine whether a simple screening technique (x-ray mammography) can diagnose breast cancer early. B. To determine if the very early diagnosis of breast cancer is really useful in improving long-term survival. C. To investigate through a prospective study of the women screened, the relationship of a wide range of paraeeters to the development of breast cancer. This is a combination statistical-epidemiological-medical study in which a study population receiving mammography at annual intervals and a control group (each group comprising 30,000 women) are being routinely followed for breast cancer experience through internal Health Insurance Plan files and through review of death certificates. Details of the techniques are given in a paper describing the methodology and initial findings of this study entitled, 'Evaluation of Periodic Breast Cancer Screening with Mammography' by Sam Shapiro, Philip Strax, and Louis Vent, Jama 195:731-738, 1966. During one reexamination cycle 40 cc of blood was taken from women in the study population and stored. Findings to date strongly suggest the usefulness of annual screening which includes mammography. Over the short run period of 6 years of follow-up, women in the study group had about one-third less mortality from breast cancer than those in the control group. The differential between control and study cases in fatality from breast cancer is almost entirely due to the exceptionally low rate among the cases detected through screening. Both the clinical examination and mammography contributed to this favorable situation but mammography, with a fatality rate of only 2% among cases detected in the absence of positive clinical findings during screening, was especially important.

BARRIER CONTRACEPTIVE PRACTICE AND MALE INFERTILITY AS FACTORS IN BREAST CANCER IN MARRIED WOMEN

A.N. Gjorgov, University of Pennsylvania, School of Medicine, Dept. of Obstetrics & Gynecology, *36th & Hamilton Walk, Philadelphia, Pennsylvania* 19174 (D-IARC-79-1022)

A case-control study is in progress to test the hypothesis that a reduced exposure to human seminal factors in the early reproductive life of women is a risk factor in breast cancer. Seminal factors can be reduced or eliminated in intercourse and/or in the ejaculate by (1) using barrier contraceptive techniques (condom, withdrawal, celibacy, long-term abstinence) and (2) male infertility. The population under study consists of 153 consecutive breast cancer patients, married and ever-married white women 35-60 years of age. The controls, 168 women with the same characteristics, matched by age and social status, come from the outpatient clinics of the same institution. Information is obtained by interview. Based on aggregate data, the relative risk-ratio of exposure to the hypothetical semen factor deficiency is 4.7 times greater in breast cancer group than in the controls. When the contraceptive methods alone are taken into account, the relative risk ratio increases up to 5.3 times. The male factor,

especially male subfertility, does not seem to play such a major role: the ratio of marital infertility is 1.5 times greater for the reference group than for the controls. About 16 percent of the women using barrier methods and 3.4 percent of women using non-barrier contraceptive methods (diaphragm, pill, IUDs, rhythm, tubal ligation and other) would develop breast cancer. The risk of developing breast cancer within the same population in the United States is about 5 times greater in women who use barrier methods than in women who use non-barrier contraceptive methods. The reduction of the incidence of breast cancer by eliminating the barrier contraceptive techniques would be not less than 50 percent in the entire population. The possibility of preventive measures within an accepted and adequate family planning program is emphasized. Analysis continues.

2.2068,
LONG-TERM MORTALITY OF STEELWORKERS
C.K. Redmond, University of Pittsburgh, Graduate School of Public Health, Dept. of Biostatistics, *4200 5th Ave., Pittsburgh, Pennsylvania* 15260 (D-IARC-79-1034)
The objective of this study is the identification of work areas, occupations, and processes within the steel industry that are associated with unusual mortality from specific diseases indicative of health hazards in the work environment. Two cohorts of steelworkers consisting of all male workers employed at seven U.S. steel plants in 1953 and 1961 respectively have been followed for mortality through 1970 with less than 1 percent untraced. Mortality rates for specific causes of death among men employed in various jobs and work areas are compared to rates for the total steelworker population with adjustment for age, race, and calendar year at risk. Reports have been prepared on coke oven workers, crane operators, and open hearth workers. Other work areas will be the subject of future reports. Methodological studies have also been prepared that discuss proportionate mortality versus mortality rates, effects of utilizing different kinds of control groups, and retiree mortality patterns as they compare to the total population-at-risk. Current phase of this investigation is concerned with updating vital status of all workers and re-evaluating the trends in cause-specific mortality patterns among men employed as coke oven workers, a group which has been demonstrated previously as having excess cancer mortality of several sites.

MORTALITY EXPERIENCE OF PRINTING PRESSMEN IN THE UNITED STATES AND CANADA
E.C. Hammond, American Cancer Society Inc., Dept. of Epidemiology & Statistics, *777 3rd Ave., New York, New York* 10017 (D-IARC-79-936)
With the assistance of the Printing Pressmen's Union, a cohort of all members of this union in 1960 has been established (this particular cohort contains some 65,000 individuals). The mortality experience of the individuals concerned is being examined. As in other studies, expected deaths will be age, year and sex specific. In a second study, a cohort has been established of all members of the union local in New York City which includes all printing pressmen employed by newspapers and similar shops ('web pressmen') in 1954. Although this cohort contains fewer than 2,000 individuals, it will be possible to undertake virtually complete tracing of all its members and to undertake detailed consideration of appropriate hospital and pathological data. Again, expected deaths will be compared with those observed, by cause. A preliminary analysis has been completed.

CANCER OF THE CERVIX IN BUFFALO AND KENMORE
S. Graham, State University of New York, Buffalo Campus, School of Social Science & Admin., Dept. of Sociology, *3435 Main St., Buffalo, New York* 14214 (D-IARC-78-718)
Early marriage, multiple marriages, early age at first pregnancy, number of pregnancies, and a variety of other factors have been found to be associated with cancer of the cervix. This study examines these associations on a community-wide basis utilizing cases of cancer of the cervix reported from all of Buffalo and suburban Kenmore, to the New York State Tumor Registry. Interviews were conducted between 1959 and 1963 for cases and a control group of women forty and over residing in random sample of households in Buffalo and Kenmore. Of particular concern in the analysis will be the comparison of approximately 1,300 white, non-Jewish controls. Analyses, which are about complete, follow a multivariate approach to assess the relative importance of those factors associated with the diseases and other approaches which consider more than one factor at a time. Briefly, we found, as have other investigators, that early marriages, early pregnancy, and having multiple marital partners enhances risk. A new finding is that cases have used the vaginal douche more frequently and over a longer period of time than controls. A paper reporting findings is being prepared.

NATIONAL CANCER INSTITUTE PROGRAM OF CANCER SURVEILLANCE, EPIDEMIOLOGY AND END RESULTS (SEER PROGRAM)
M.H. Myers, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Biometry Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205 (D-IARC-78-697)
The SEER Program was developed in response to the National Cancer Program requirements for assessing, as currently as possible, the magnitude of the cancer problem in the United States and for identifying factors related to cancer risk and/or patient survival. The 'cancer problem' has been interpreted to include: (1) newly diagnosed cancer cases that might have been prevented by altering host or environmental conditions, and (2) deaths due to cancer that might have been prevented by earlier cancer diagnosis coupled with optimal therapeutic approaches. Therefore, the SEER Program has among its objectives: (1) To assemble and report on a periodic basis, estimates of cancer incidence in the United States. (2) To monitor annual cancer incidence to identify unusual changes in specific forms of cancer occurring in groups defined by parameters of geographical, demographic and social characteristics of the population. (3) To provide continuing information on changes over time in extent of disease at diagnosis, trends in therapy and associated changes in cancer patient survival and (4) To promote the development of hypotheses and specific studies designed to identify cancer aetiological factors (environmental/occupational, sociocultural, etc.) and factors related to patient survival.

STATISTICAL METHODS IN CANCER EPIDEMIOLOGY
N. Mantel, George Washington University, Biostatistic Center, Dept. of Statistics, *7979 Old Georgetown Rd., Bethesda, Maryland* 20014 (D-IARC-79-852)
The spontaneous occurrence of cancer in humans, or induced occurrence in laboratory animals, reflects the interplay of many variables. Also multivariate in nature are the factors influencing survival times or remission times of individuals with cancer, whether treated or left untreated. The multivariate statistical problems which arise may relate to identifying individually important variables which may be causative, making prognosis of survival or other predictions for cancer patients with a specified multivariate vector, and seeking to identify optimal therapeutic procedures for such patients. Data available for such analyses may be prospective or retrospective in nature, and for the prospective case will generally involve incomplete observations. Recent developments in mathematical models and statistical approaches for relating response to multivariate regressors, specifically models involving hazard functions and generalized logistic regression, open the way to handling such problems, and it is the effective use of such models and approaches that I plan to study. In some instances these approaches may bear modification as, say, using a classification approach when data are abundant but variables to be studied few in number. I anticipate that tie-ins with other problems of cancer epidemiology will develop. Related, or variant methods, may be appropriate in the study of potential environmental carcinogens. Methods for safety evaluation of such agents represent a preventive epidemiology approach.

RESPIRATORY EFFECTS OF CHLOROMETHYL ETHERS

W. Weiss, Hahnemann Medical College & Hospital, School of Medicine, Dept. of Medicine, *235 N. 15th St., Philadelphia, Pennsylvania* 19102 (D-IARC-79-1030)

A prospective study of 125 male workers at a chemical plant by periodic chest x-rays and questionnaires was conducted from 1963 to 1968 to investigate the suspicion that some were exposed to a carcinogen. In 1965 a spirogram was done in 103 men. Follow-up has been continued since 1968. Retrospective studies during 1971-74 revealed that 88 men had been exposed to chloromethylmethylether (CMME) containing bis-chloromethyl ether as a contaminant. Each man was assigned an exposure index and the men were divided into a non-exposed and three exposed groups according to the magnitude of the index. The groups were similar except that the most heavily exposed group had more non-smokers and more light cigarette smokers than the other groups. The prevalence of chronic cough and expectoration increased with increase in exposure index. Mean ventilatory function was normal in all groups. Exposure diminished with time as the process was increasingly contained. From 1963 to 1968 the prevalence of chronic cough decreased while the prevalence of dyspnea increased. Eleven men developed lung cancer in the 10 year period from 1963 to 1972 inclusive and there was a strong dose-response relationship. Of the 20 most heavily exposed men, 30 percent developed lung cancer. There was an inverse relationship between smoking habits and the risk of lung cancer. All of the cancers were small cell in type. Observation of the cohort is continuing.

EPIDEMIOLOGY OF HISTOLOGIC TYPES OF LUNG CANCER

W.E. Morton, Oregon State Higher Education System, University of Oregon Health Sciences Center, School of Medicine, Dept. of Public Health & Preventive Medicine, *3181 S.W. Sam Jackson Park Rd., Portland, Oregon* 97201 (D-IARC-79-1017)

The continued annual increases in lung cancer mortality seem excessive in view of the static smoking behavior during the past decade, suggesting that other environmental influences need more study. A pilot study of incidence during 1968-1972 among residents of three counties in the Portland metropolitan area identified 2,002 cases. Most were smokers (97% in males, 80% in females); a minority had a family history of cancer (males 32%, females 42%). The different histological types exhibited major differences in their socioeconomic, geographical, and occupational risk patterns, suggesting that perhaps they should be regarded as distinct diseases. Major sex differences in socioeconomic patterns of risk suggested the importance of occupational confounding among men. Occupational risk differences between both sexes far exceeded those noted with other risk factors, suggesting that occupational factors deserve primary emphasis in future efforts in lung cancer control. Several occupations had high risk for three or more histological types, but much more common was the situation in which only a single histological type was excessively frequent in the presence of an unremarkable rate for total lung cancer. Thus the identification of occupational hazards for lung cancer will become significantly more sensitive if histology-specific rates are used rather than total rates. It is hoped to extend this study through 1977 and beyond and to initiate more limited investigations of specific occupational and industrial hazards. Correlations with community air quality indices will also be sought.

STUDY OF ANIMAL CONTACTS IN LEUKEMIA

I.I. Kessler, University of Maryland, Baltimore Professional Schools, School of Medicine, Dept. of Epidemiology & Preventive Medicine, *655 W. Baltimore St., Baltimore, Maryland* 21201

Recent evidence has suggested that there may be significant relationships between leukemia occurring in household pets and that occurring in humans. The present analysis, conducted in collaboration with Dr. Hipolito Pabon of Colombia, is based upon the Tri-State Leukemia Survey of a decade ago. Detailed animal contact histories of large number of leukemic children as well as controls were taken. The results are being analyzed in terms of the numbers and types of animal contacts among the leukemic children and controls during their life-times as well as during the relevant pregnancies of the mothers. All the data in this study has been processed and a master card has been prepared for the analysis of the findings.

PROSTATIC CANCER EPIDEMIOLOGY WITH SPECIAL REFERENCE TO THE UNITED STATES AND JAPAN

L.T. Kurland, Mayo Clinic, Medical Statistics & Epidemiol, *200 1st St. S.W., Rochester, Minnesota* 55901 (D-IARC-79-891)

Former international studies have shown that there is a rapid increase in the incidence rates of prostatic cancer for persons over 50 years of age; 80% of the cases occur in persons age 65 and older; mortality rates have been highest among U.S. Non-whites followed by South Africa, France, Canada, and U.S. Whites, with Japan having the lowest rate; in Israel a higher mortality has been reported among occidental than among the oriental population; and there is a positive statistical association between prostatic cancer and pancreatic cancer, and a negative association with stomach or liver cancer. An attempt will be made to discover factors related to the development of prostatic cancer with special emphasis on reported differences in the incidence and mortality rates in the United States and Japan data for the period 1950 through 1975. The reliability of the mortality and morbidity reports have been evaluated and it is suggested that suspected aetiologic factors such as sexual activity, cigarette smoking, and fat intake will be compared among patients and controls in the two countries.

EPIDEMIOLOGY OF CANCER IN A LARGE NON-SMOKING POPULATION

J.L. Lyon, Utah Higher Education System, University of Utah, School of Medicine, Dept. of Family & Community Medicine, *1400 E. 2nd S., Salt Lake City, Utah* 84112 (D-IARC-79-1057)

Approximately 73 percent of the population residing in the State of Utah are members of the Church of Jesus Christ of Latter-Day Saints (LDS, commonly called Mormons). The Church proscribes the use of alcohol, coffee, tea, and tobacco. Using a population-based cancer registry with data from 1966 onward, cancer incidence is estimated to be 20 percent less in the LDS than the non-LDS within the state. Major contributions to this decrease are made by cigarette-associated sites. However, unexplained differences in the area of uterine cervical cancer, stomach and colon cancer exist. Decreases in cancer unrelated to religion are also noted, such as cancer of the pancreas. Currently, analysis of registry is being carried out to better characterize the differences by socioeconomic class, urban-rural differences, etc. In the near future, case-control studies to better identify specific etiologic agents will be mounted in ovarian cancer, cervical cancer, pancreatic cancer, and colorectal cancer.

CANCER MORTALITY AMONG WORKERS EXPOSED TO CUTTING OIL MIST

P. Decouffle, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., *9000 Rockville Pike, Bethesda, Maryland* 20205 (D-IARC-79-845)

The objective of this study is to determine the cancer experience of workers exposed to cutting oil mist. The study group is comprised of 24,000 men who worked for at least one year in a blue-collar job at a particular plant during the period 1938-1967. Follow-up for mortality was completed through 1967 with less than 5 per cent untraced. Cause-specific mortality rates for men exposed for varying periods of time at different oil mist exposure levels are compared to mortality rates for the general U.S. population and to rates for a non-exposed group from the same plant. Future emphasis will be on detailed cancer sites and specific respiratory diseases. Follow-up of the cohort is being extended beyond 1967.

EPIDEMIOLOGIC SURVEY ON HAWAII RESIDENTS

L.N. Kolonel, University of Hawaii System, Manoa Campus, School of Public Health, Dept. of Biomedical Sciences, *Spalding Hall, Room 255, Honolulu, Hawaii* 96822 (D-IARC-79-786)

In 1975, a brief epidemiological questionnaire was added to the on-going Health Survey of Hawaii, a representative, statewide survey patterned after the US National Health Survey. About 6,000 households are surveyed annually, and the epidemiological questionnaire will be administered for a period of 5 years. This questionnaire seeks information on smoking, drinking and dietary habits, which can be related to various demographic data (age, sex, race, place of residence, education, income, etc.), which are collected routinely in the survey. Data from the first year of the epidemiological survey are now being analyzed in relation to some of the interesting differences observed in cancer incidence and mortality among the various ethnic groups in Hawaii. The cohort developed through this survey will be followed prospectively for cancer risks in relation to antecedent dietary and smoking habits.

EPIDEMIOLOGY OF HEPATIC ANGIOSARCOMA

H. Falk, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, Cancer & Birth Defects Div, *1600 Clifton Rd. N.E., Atlanta, Georgia* 30333 (D-IARC-79-779)

This project started about four years ago with the discovery of the association between hepatic angiosarcomas and long-term exposure of industrial workers to vinyl chloride. Subsequently, a survey of pathologists in the USA was conducted and to date about 250 cases of human hepatic angiosarcoma have been identified and the slides reviewed. As noted, some of these cases were caused by vinyl chloride. Other cases were caused by or associated with exposure to Thorotrast or to arsenical compounds. The majority of the cases have no known environmental or industrial aetiology. The epidemiological study which is continuing involves obtaining detailed work and exposure histories from all these patients or from their living relatives. The pathological aspects of the study are conducted by Drs. Thomas, Popper and Teller. The epidemiological aspects are under Dr. Falk and other epidemiologists at the Center for Disease Control in Atlanta, Georgia.

CANCER AND ORAL CONTRACEPTIVES

B. MacMahon, Harvard University, Boston Campus, School of Public Health, Dept. of Epidemiology, *55 Shattuck St., Boston, Massachusetts* 02115 (D-IARC-79-866)

In 1970, mail questionnaires were sent to 97,364 married women in the Boston metropolitan area inquiring about their oral contraceptive usage. A second follow-up questionnaire was sent in 1973 to all users and a matching number of non-users. To evaluate the relationship between oral contraceptive use and breast disease, all women diagnosed with benign or malignant breast disease were identified and matched to the cohort. The surveillance period was 1969 to 1972. A significantly lower risk of fibrocystic disease among long-term users of oral contraceptives for all age and parity strata was found. Hospital surveillance was continued through 1977 and the resulting data are now being analyzed.

STUDIES OF CANCER EPIDEMIOLOGY IN LATIN AMERICA

P. Correa, Louisiana State University, Medical Center, School of Medicine, Dept. of Pathology, *1542 Tulane Ave., New Orleans, Louisiana* 70112 (D-IARC-79-821)

The objective of this project is to identify problems of cancer epidemiology by means of cancer registration schemes and follow some of them with pathology and epidemiology studies in more depth. Special emphasis is given to cancer of the oesophagus, stomach, gallbladder and large bowel. Cancer registries participating in this programme are located in Cali (Colombia), Recife (Brazil), Sao Paulo (Brazil), and La Plata (Argentina).

MORTALITY EXPERIENCE OF CERAMIC TILE SETTERS IN THE NEW YORK CONSTRUCTION INDUSTRY

I.J. Selikoff, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Community Medicine, *5th Ave. at E. 100th St., New York, New York* 10029 (D-IARC-79-944)

We have been interested in obtaining information concerning the mortality experience of individuals working in the construction industry in New York, potentially indirectly exposed to asbestos dusts within that industry, but not directly so exposed by virtue of the nature of their own work. One such group has been the ceramic tile setters, a 'finishing trade', working in the same buildings as trades using asbestos materials in other work, but whose own materials do not contain asbestos. We have established a cohort of all ceramic tile setters in the New York construction industry in 1955 who were members of their union for at least five years. This was done with the cooperation of the Tile Setters' Union. The mortality experience of this cohort is being investigated through 1973. A sample of 100 tile setters was also clinically examined.

CANCER MORTALITY AFTER ARSENICAL THERAPY FOR SYPHILIS

B.S. Pasternack, New York University, School of Medicine, Dept. of Environmental Medicine, *550 1st Ave., New York, New York* 10016 (D-IARC-79-942)

The object of this study is to investigate the role of arsenic in carcinogenesis by comparing the cancer mortality rates for patients who received arsenicals vs. penicillin as syphilitic therapy. Complete clinical records are available for about 2,800 patients treated at Bellevue Hospital in New York City in the early 1940's half of whom were given arsenicals. This is the only project known where precise characterization of human arsenical exposures and comparable controls are available on such a large scale, with a 30-year follow-up. Social security numbers were available for these 2,800 patients, so deaths are being ascertained through the Social Security Administration files. Causes of death will be established through death certificates and hospital records.

EPIDEMIOLOGY OF CANCER OF THE CERVIX IN HIGH RISK POPULATIONS

S. Graham, State University of New York, Buffalo Campus, School of Social Science & Admin., Dept. of Sociology/Social & Preventive Medicine, *3435 Main St., Buffalo, New York* 14214 (D-IARC-79-922)

This study examines factors that have been found to be associated with cancer of the cervix: large number of sex partners; contraceptive types which expose women directly to their partners; early age at first intercourse, marriage, and pregnancy, number of pregnancies and use of the vaginal douche. These factors will be examined in women known to be at higher than usual risk of cancer of the cervix: Blacks and, because of their low socioeconomic status, Chicanos. In addition, a number of investigators have inquired into the presence of microorganisms or antibodies to them in patients with cancer of the cervix and in controls. Almost always, cases reveal much larger percentages possessing antibodies to herpes type 2 virus. We wished to examine whether cases could be distinguished from controls on the presence of Herpes in instances where there has been only one sexual partner as well as on instances where there have been many. It would also be of interest to know whether among cases with only one and those with many partners the proportion of women with antibodies is the same, and higher than among controls with one or many partners. If these conditions were obtained, it would suggest that herpes type 2 virus is strongly implicated. Our sources of lower social class Chicano and black women with cancer of the cervix and appropriate controls are the Los Angeles County - University of Southern California Hospital, the Martin Luther King Jr. Hospital in Los Angeles, and California Hospital. Two hundred fifty black patients with invasive disease and a like number of Chicano patients, plus equal numbers in each group of carcinoma in situ will be interviewed. Controls will consist of women patients at the same hospitals, matched on age, with non-neoplastic, non-pelvic diseases. Each case and control will have 15 ml. of blood drawn. Antibody titer to herpes virus types 1 and 2 will be quantitated using a modification of measurement of release of 51 chromium. Data collection is ongoing.

INCIDENCE OF SECOND SQUAMOUS CANCERS OF THE HEAD AND NECK IN SMOKERS AND THOSE WHO HAVE CEASED SMOKING

C.N. Moore, University of Louisville, School of Medicine, Dept. of Surgery, *101 W. Chestnut, Louisville, Kentucky* 40202 (D-IARC-79-818)

The aim of the study is to compare equal groups of individuals who have been smokers and who have been cured of one squamous cancer of the head and neck (excluding skin) dividing them into two subgroups: (1) those who continue to smoke three years after the control of the first cancer; and (2) those who cease smoking with the discovery of their first cancer. The incidence of second cancer in the two groups can then be compared over a long period extending to 20 years or the lifetime of most patients.

MORTALITY EXPERIENCE OF WORKERS IN THE PAINTING TRADES IN THE U.S. AND CANADA

I.J. Selikoff, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Community Medicine, *5th Ave. at E. 100th St., New York, New York* 10029 (D-IARC-79-947)

Workers in the painting trades have a variety of exposures to known or suspected carcinogenic agents, ranging from asbestos dusts to benzene and other solvents. Vinyl chloride exposure has also been identified in some circumstances. With the cooperation of the Painters' Union in the United States and Canada, we are establishing a cohort of all registered members of the union in 1965. These individuals will be followed prospectively from that point onwards and their mortality experience analyzed. It will probably be possible to categorize the full cohort by trade (general painters, dry wall construction workers, sandblasters, iron painters, paper hangers, wood finishers, paint makers, etc.) and the mortality experience of the various groups will be separately considered. Another cohort of all members of the Painters' Union in New York City in 1960, who had maintained membership for at least five years, is also available and will be studied prospectively from that point to the present. In order to obtain background information concerning types of lesions which may be of particular interest, 1,000 members of the union have already been examined clinically, with appropriate laboratory studies, and another 2,500 men will be studied during the two coming years. In addition, industrial hygiene studies of the environment in the painting trades are being undertaken.

LONG-TERM PROSPECTIVE OBSERVATION OF ASBESTOS INSULATION WORKERS IN THE NEW YORK METROPOLITAN AREA

I.J. Selikoff, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Community Medicine, *5th Ave. at E. 100th St., New York, New York* 10029 (D-IARC-79-946)

On January 1, 1943, there were 632 members of the Asbestos Insulation Workers' Union in the New York

metropolitan area. The entire cohort has been followed prospectively since. All those alive January 1, 1963, were clinically investigated and, among other things, cigarette smoking habits were recorded. Mortality experience of the cohort is being analyzed. By January 1, 1963, 262 individuals had died and approximately 250 more deaths had been recorded by the end of 1976. In addition, 890 workers joined this union between January 1, 1943, and December 30, 1962, and their experience is also being studied epidemiologically and clinically. Their mortality experience will reflect risk past World War II.

2.2099,

CANCER EXPERIENCE OF VINYL CHLORIDE POLYMERIZATION WORKERS

I.J. Selikoff, City Universitv of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Community Medicine, *5th Ave. at E. 100th St., New York, New York* 10029 (D-IARC-79-945)

During 1974, over 1,200 vinyl chloride polymerization workers were examined in a clinical survey, and a great deal of clinical, biochemical, x-ray and pulmonary function data recorded. In addition, details concerning vinyl chloride and other chemical exposures were noted, with complete occupational histories (including other than vinyl chloride employment). This cohort of vinyl chloride-exposed workers (approximately 1/5 of the vinyl chloride polymerization workers employed in the U.S.) is being observed prospectively. Their mortality experience will be analyzed and compared with expected deaths by cause.

EPIDEMIOLOGICAL STUDIES OF URANIUM MINERS AND MILL WORKERS

V.E. Archer, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Health Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (D-IARC-79-982)

Uranium miners have been found to have an excess of lung cancer and mill workers to have an excess of lymphomas. A much larger group of mill workers is now being studied by a retrospective cohort study to determine the magnitude of the lymphoma excess. Identification of the substance responsible is being attempted. Two groups of uranium miners are being studied, one of about 4,300, and a much larger one of about 15,000. These groups are being used to determine exposure-response curves, and the different factors which influence the shape of those curves; effects of exposure on the sex-ratio of offspring, the effect of age at first exposure on incidence and latent period, and the dose rate effect.

STUDY OF THE INCIDENCE AND NATURAL HISTORY OF GENITAL TRACT ANOMALIES AND CANCER IN OFFSPRING EXPOSED IN UTERO TO SYNTHETIC ESTROGENS

R.H. Kaufman, Baylor College of Medicine, School of Medicine, Dept. of Obstetrics & Gynecology, *1200 Moursund Ave., Houston, Texas* 77025 (D-IARC-79-1049)

Synthetic estrogenic substances (DES) have been administered to pregnant women for approximately three decades, primarily with the intent of preventing spontaneous abortions. From 250,000 to 1,000,000 females and an equal number of males were exposed to DES during gestation. Recently, studies have been reported linking such exposure to DES with development of specific malignancies and other abnormalities of the female lower reproductive tract. Whether significant abnormalities of the genitourinary system also occur among males is not known. The aims of this project are to follow the course of development of persons exposed to DES in utero (and comparison groups of unexposed persons) in order to detect the occurrence of and secure treatment for possible anomalies or malignancies which may arise. Over a period of five years of follow-up, for subgroups at various ages when entering the project, the experience of groups remaining free of all pathology, developing new pathology, continuing with pathology similar to that at entry, or treated in accordance with one or more special protocols, will be analyzed. The risk of these outcomes will be determined among cohorts where DES exposure status is known, and treatment protocols may be devised and implemented for particular outcomes which are observed.

2.2106,

INCIDENCE AND NATURAL HISTORY OF GENITAL TRACT ANOMALIES AND CANCER IN OFFSPRING EXPOSED IN UTERO TO NONSTEROIDAL ESTROGEN

L.T. Kurland, Mayo Clinic, Dept. of Epidemiology & Med Statistics, *200 1st St. S.W., Rochester, Minnesota* 55901 (D-IARC-79-890)

This study has been initiated by the National Cancer Institute through contracts with collaborating clinical centers and a coordination center. It is intended to assess, comprehensively, the magnitude and severity of the health hazards to exposed offspring which may result from the administration of exogenous, nonsteroidal estrogens (hereafter denoted 'DES') to pregnant women over the past three decades in the United States. Following review of available medical records in selected areas of the country, exposed offspring will be identified and subsequently contacted; or, subsequent to subjects presenting independently or by referral from physicians, exposure or nonexposure to DES will be verified in retrospect for some proportion of subjects. Through either mechanism, cohorts of known exposed subjects of both sexes will be identified and requested to enter the project. Unexposed cohorts of both sexes will also be contacted. The potential course of subsequent events is identical in the exposed and unexposed cohorts. Through standardized interviews and clinical and laboratory examinations, subjects will be classified at entry to the project as free of relevant pathology to date, or as having currently or by documented past history one or more of several critical diagnoses, generally identified as vaginal adenosis (females only), or neoplasia or malformation of the genitourinary or lower reproductive tracts. Other specific diagnoses of interest may be added. Ascertainment of changes in diagnoses by interview and examination will be repeated regularly over the period of follow-up, which will be a minimum of 5 years for each participant.

PROSPECTIVE STUDY OF THE RELATIONSHIP OF HORMONAL AND SOCIOLOGICAL FACTORS TO THE DEVELOPMENT OF CANCERS OF VARIOUS SITES

A.M. Lilienfeld, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Epidemiology, *615 N. Wolfe St., Baltimore, Maryland* 21205 (D-IARC-79-833)

The objective is to see if serological changes found in cancer patients antedate the development of their disease by comparing serum specimens from patients and controls taken at the same time and before cancer had developed in the patients. Serum was collected in 1974 from nearly 26,000 volunteers in Washington County, Maryland, and stored at minus 100 degree F. In addition to identification data, information was collected on marital status, education, smoking, date of last menstrual period (for women), and medications, with special emphasis on hormonal preparations. A cancer registry has been maintained in the county since 1958. When sufficient numbers of cases have developed since 1974, serum of cases and matched controls will be withdrawn from storage to be examined for hormone, antibody, protein, or trace metal levels, as indicated by previous concurrent case-control studies.

IDENTIFICATION OF HIGH-RISK OCCUPATIONAL GROUPS

I.I. Kessler, University of Maryland, Baltimore Professional Schools, School of Medicine, Dept. of Epidemiology & Preventive Medicine, *655 W. Baltimore St., Baltimore, Maryland* 21201 (D-IARC-79-832)

Evidence from the laboratory as well as from clinical observations and epidemiological studies is substantiating earlier findings on the role of occupational factors in human carcinogenesis. Recent clinical and epidemiological evidence relating environmental exposure to such materials as asbestos, vinyl chloride, radiation, etc. strongly suggests that a major effort should be undertaken to identify occupational agents which may be responsible for human cancer, parkinsonism and other chronic disease. An etiologically

meaningful analysis of occupational histories must have at least two characteristics: first, the analysis must be conducted in such a fashion as to permit comparisons with the findings of previous investigators; and second, the analysis must make identification of potentially dangerous occupational exposures possible. To accomplish these dual purposes, two completely independent analyses of occupational data are being undertaken, the first in accordance with the United States Census Bureau Index of Industries and Occupations, making it possible to compare results with those of previous investigators who have used the same index, and the second classifying all occupational exposures judgmentally, for the purpose of identifying all possible potentially hazardous occupational or industrial categories. After identifying specific occupational hazards in this fashion, previous investigators could be contacted with a view to reanalyzing their data in terms of the potentially dangerous occupations or industries newly identified.

AN INVESTIGATION OF LYMPHOID TISSUES IN NEOPLASIA

I.I. Kessler, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Epidemiology, *615 N. Wolfe St., Baltimore, Maryland* 21205 (D-IARC-78-663)

This study is designed to measure the risk of subsequent development of cancer in persons who have undergone surgical removal of the vermiform appendix and/or palatine tonsil and to compare this risk with that in a control population. There has been a recent increase of interest in the lymphatic system and its relationships to normal and abnormal growth processes. To this end, we are attempting to trace a cohort of approximately 5,000 persons who were appendectomied and another cohort of similar number who had their tonsils removed at the Johns Hopkins Hospital from 1925 to 1936. When traced, the mortality and, perhaps, incidence of cancer among them will be compared to that of a matching control group undergoing other types of surgery at Johns Hopkins during the same period of time. Both the appendectomy and tonsillectomy cohort have been identified and the basic data relating to them entered into punched cards. The tonsillectomy cohort data are now being validated and preparations made for follow-up as to survival and case-specific mortality.

AN INVESTIGATION OF THE MALE ROLE IN CERVICAL CANCER

I.I. Kessler, University of Maryland, Baltimore Professional Schools, School of Medicine, Dept. of Epidemiology & Preventive Medicine, *655 W. Baltimore St., Baltimore, Maryland* 21201 (D-IARC-79-830)

Studies utilizing a number of different approaches suggest that the male sex partner may play a role in the aetiology of cervical cancer. Demographic analyses reveal higher cervical cancer mortality rates among married and previously married women than among single women or virgins. A possible association between penile and cervical cancer has been demonstrated. Considerable evidence has accumulated on the relationship between cervical cancer and the venereally transmitted genital herpes virus, HSV-2. The results of these studies have increased the likelihood of a significant male role in cervical carcinogenesis. The study is designed to provide an additional test of the venereal hypothesis in the pathogenesis of cervical neoplasia. The approach represents an attempt to answer the following question: Is the risk of developing cervical cancer increased among the wives of men who - at sometime in their lives - were married to other women who developed cervical cancer? The study begins with the identification of a large group of women who had cervical cancer in Greater Baltimore during the past 20 years. The husbands of these women are investigated to the extent of identifying all their previous and subsequent wives ('case' wives). A random sample of 'control' wives, similar to the 'case' wives in demographic and marital characteristics is then selected. The cohorts of 'case' and 'control' wives are traced prospectively to death or survival at a recent point in time. The ultimate risk of cervical neoplasia among the two cohorts is compared, utilizing actuarial techniques. This approach affords a direct test of the role of any venereally transmitted male factor in cervical cancer, whether it be viral, chemical or otherwise.

TRI-COUNTY STUDY OF CANCER OF THE MOUTH, OESOPHAGUS, PHARYNX, LARYNX, STOMACH, COLON AND RECTUM

S. Graham, State University of New York, Buffalo Campus, School of Arts & Letters, Dept. of Sociology/Social & Preventive Medicine, *3435 Main St., Buffalo, New York* 14214 (D-IARC-79-920)

There have been suggestions that diet, alcohol ingestion, oral conditions, and smoking are related to cancer of the mouth, oesophagus, and stomach, and that alcohol ingestion and smoking are related to cancer of the larynx. These relationships are the subject of this inquiry. To avoid hospital related bias and to obtain detailed information on each case, all new cases in Erie, Niagara and Monroe Counties in New York State will be interviewed. It will take four years to obtain enough (about 300) cases of cancer of the oesophagus and larynx for males, and two years to obtain the buccal and stomach cancer cases necessary for analysis. Cancers of the oesophagus and larynx are so rare in females that the inquiry will be limited to buccal and stomach cancer among females. All controls will be matched on age (within five years) and sex and reside in the neighborhoods of the cases. To obtain all corroborative evidence possible as to dietary habits of subjects, spouses or other individuals who live with or cook for the subjects will be interviewed. A multivariate analysis of the results will be carried out. Data collection has proceeded well in the past year. We have interviewed 744 cases, comprised of 161 mouth, 97 oesophagus, 169 larynx, 28 pharynx, 141 stomach, 111 colon, and 37 rectum cancers. In addition, 599 controls, 112 control spouses and 119 case spouses have been interviewed. Data collection will continue as scheduled over the next year. Preliminary analysis of 100 case/spouse and 100 control/spouse pairs to determine extent of agreement with regard to the subjects' dietary habits is under way.

2.2113,

SOCIO-ECONOMIC AND DEMOGRAPHIC FACTORS THAT INFLUENCE HEALTH STATUS IN THE VICINITY OF ENERGY (ABBREV)

D. Grahn, Argonne National Lab., Division of Biological & Medical Research, *9700 S. Cass Ave., Argonne, Illinois* 60439 (D-IARC-79-797)

The long-range objective of the study is to develop predictive relationships between the socio-economic and demographic characteristics of regional and local populations and the general health status of these populations. Special attention has been given to the identification of the causes of mortality that may be related to the effluents from existing or proposed major energy systems. A procedure for standardizing mortality variations using county-level socio-economic and environmental characteristics is being developed. The relationships between selected measures of population health and socio-economic, demographic, and environmental variables are under examination. The data are derived from 1970 Census Data, 1969-1971 U. S. Vital Statistics, and recent pollution, climate, cigarette and alcohol consumption data. This data base is fully developed for 191 counties within an 80 Km radius of 15 power generation sites. These sites sample the diversity of US socio-economic, demographic, and geographical features. Presently, the data base is being extended to include the entire U.S. Multiple regression analysis of the selected total and cause-specific mortality measures (sex-race specific; age-standardized death rates, expectation of life at various ages, infant mortality) on the various independent variables has explained about on-half of the variance in the health measures. It is anticipated that the resulting equations can assist state and local governments in the anticipation of health care requirements for changing socio-economic and environmental factors.

2.2114,

CHILDHOOD ENVIRONMENT AND RISK OF HODGKIN'S DISEASE

B. MacMahon, Harvard University, Boston Campus, School of Public Health, Dept. of Epidemiology, *55 Shattuck St., Boston, Massachusetts* 02115 (D-IARC-79-864)

The objectives of this study are (1) to evaluate the hypothesis that risk of Hodgkin's disease is a function of factors in the childhood environment which inhibit infectious transmission; in particular, family size, birth order, and social class; (2) to re-evaluate the association between tonsillectomy and Hodgkin's disease; (3) to evaluate occupational exposures and Hodgkin's disease; (4) to establish a serum bank. This is a two-part population-based case-control study. Part I is conducted in a defined population in eastern Massachusetts. A 4 1/2 year incidence case series has been identified and surviving cases interviewed at home. Age- and sex-matched controls are drawn from the general population and similarly interviewed. Siblings of cases comprise a second control group. Sera are obtained from cases and sibs. Part II is conducted in a defined population in Detroit, Michigan. A similar incidence series has been identified and information is gathered from live cases and sibling controls by mail questionnaire.

RISK OF NEOPLASIA IN NEIGHBORHOOD ASBESTOS DISEASE

E.C. Hammond, American Cancer Society Inc., Dept. of Epidemiology & Statistics, *777 3rd Ave., New York, New York* 10017 (D-IARC-79-937)

It is known that mesothelioma can occur in relatives of asbestos workers. However, it is not known whether or not mesothelioma or lung cancer occurs with greater frequency in persons with low-level exposure, for example, those living near an asbestos plant. We have established cohort of all males over the age of 18 living within a half mile of an asbestos plant in Paterson, New Jersey, 1942-1943; there were approximately 2,500 such individuals. As a control group, we have listed a cohort of men with identical qualifications in another neighborhood of the same city, with similar social strata, but without an asbestos facility. All members of both cohorts are being traced through 1974 and their mortality experience evaluated. We have successfully traced over 95 percent of both groups. In addition, lung tissue of those who have died is being analyzed for its asbestos content, quantitatively, and settled dust in homes at varying distances from the index factory, taken from attic rafters, etc., is being studied for its asbestos fiber burden. In both the epidemiological and environmental investigations, workers employed in the factory and their families are excluded. The first mortality analyses of these data are now completed. Total mortality, total cancer and lung cancer deaths did not differ in the two neighborhoods 20-35 years after first exposure. Follow-up will continue.

EPIDEMIOLOGY OF MALIGNANT MELANOMA

S. Graham, State University of New York, Buffalo Campus, School of Social Science & Admin., Dept. of Sociology/Social & Preventive Medicine, *3435 Main St., Buffalo, New York* 14214 (D-IARC-79-921)

The incidence of malignant melanoma has increased markedly over the past thirty years. The male incidence per 100,000 in Upstate New York has increased from 1.3 in 1941 to 3.4 in 1970. In the same period female incidence rates increased as well. This study aims to examine the effect of sunlight exposure, geography, ethnicity, genetics, hormones, exposure to chemical carcinogens and irradiation on the development of the disease. Cases and controls are being interviewed at Roswell Park Memorial Institute. We plan to continue to interview cases as they occur over a period of five years, until we have approximately 800 cases. Control matched 2 for 1 on age and sex with cases are patients with neoplasms probably unrelated to melanoma, e.g., cancer of the lung and colon. Data collection is on-going. We have interviewed 357 melanoma cases and 375 controls. A preliminary analysis is being planned.

GENITOURINARY CANCER IN MARRIED COUPLES

S. Graham, State University of New York, Buffalo Campus, School of Social Science & Admin., Dept. of Sociology, *3435 Main St., Buffalo, New York* 14214 (D-IARC-78-716)

The aim of this study was to test the hypothesis that women with cancer of the cervix might be more likely than others to have husbands with cancer of the prostate, penis, urethra, bladder, or testis. The names, ages, and addresses of approximately 2,500 women diagnosed between 1950 and 1954 with cancer of the cervix in upstate New York were obtained from the Tumor Registry of the Bureau of Cancer Control. The names and addresses of husbands of cervix cancer cases were obtained and matched against the Tumor Registry computer tapes which contain names of males with genitourinary cancer in the years since 1950. The number of cases found among husbands will be compared with the number expected in the normal population, using age-specific rates for each site; the observed number of male cases with each cancer was found to be within the expected 95 percent confidence interval range. The number of cases observed at each sexual site, with the exception of penis, was at the low end of the confidence interval for the expected numbers. In the case of the penis, the opposite was true: the expected number was 0.66 and 2 cases were observed. The incidence of genital site cancers in wives of a group of 256 males with cancer of the penis from 1960-1964 is now being examined. Preliminary results suggest a higher than expected incidence of genital cancers in these females.

MORTALITY EXPERIENCE OF BRAKE REPAIR AND BRAKE MAINTENANCE WORKERS IN NEW YORK CITY

W.J. Nicholson, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Community Medicine, *5th Ave. at E. 100th St., New York, New York* 10029 (D-IARC-79-940)

Investigations have demonstrated that brake repair and brake maintenance workers have significant exposure to asbestos in the course of their work. Random instances of pleural mesothelioma have been observed among such workers. It is not known whether these are indicators of more widespread problems. The matter is of some importance, first because of the large numbers of workers employed in this industry, including those occasionally exposed in brake repair and brake maintenance jobs while more generally occupied in automobile repair and, second, because of the interest in the general question of whether dusts from brake use have biological effects in general as environmental contaminants. We have established a cohort of all members of the United Automobile Workers' Union in New York City employed in brake maintenance and brake repair work in the various garages and automobile preparation facilities in New York, registered on the Union's Rolls for 1960 and having been so recorded for at least five years. It is our intention to examine the mortality experience of this cohort, 1960-1975, to provide initial data concerning possible asbestos hazard. Concurrently, we are clinically examining brake repair and brake maintenance workers and have undertaken a variety of industrial hygiene studies.

OCCULT CARCINOMA OF THE THYROID GLAND

F.H. Fukunaga, Kuakini Medical Center, Central Laboratory, *347 N. Kuakini St., Honolulu, Hawaii* 96817 (D-IARC-79-784)

A comparative study of occult carcinomas of thyroid glands was done to evaluate relative prevalence in the Japanese living in Hawaii (24%), and in Northern Japan (28%), Canada (5%), Columbia, South America (5.6%) and southern Poland (9%). The Japanese were found to have a much higher prevalence of these lesions although the prevalence of clinical cancer was not increased. The project is being continued in the Hawaii-Japanese, and various environmental factors such as diet will be analyzed. Other races in Hawaii are also being studied.

SELENIUM OCCURRENCE AND HUMAN CANCER MORTALITY - FAT AND BEEF CONSUMPTION AND HUMAN CANCER MORTALITY

R.J. Shamberger, Cleveland Clinic Hospital, Dept. of Biochemistry, *9500 Euclid Ave., Cleveland, Ohio* 44106 (D-IARC-79-1015)

The aim of this study is to relate selenium occurrence to human cancer mortality. Crude and some age-adjusted mortality show an inverse relationship to selenium bioavailability. Age-adjusted mortality for various cities and states in the United States has been obtained, but less than state-wide data is difficult to obtain. We would like to relate selenium in blood or bioavailability in various countries throughout the world. A major report has appeared in the Arch. of Environ. Health 31:231-235, 1976.

CASE-CONTROL STUDY OF USE OF OXIDATIVE HAIR DYES AMONG FEMALE CANCER PATIENTS

K.M. Stavraky, University of Western Ontario, Faculty of Medicine, Dept. of Epidemiology & Preventive Medicine, *1151 Richmond St., London, Ontario, Canada* N6A 3K7 (D-IARC-79-80)

This case-control interview study will attempt to determine whether women with cancers at the sites listed below have a history of more frequent exposure to oxidative hair dyes than women who are of the same age and social class, but who are either healthy or hospitalized for illnesses other than cancer. Cancer patients will be interviewed at both the Princess Margaret Hospital Toronto, and the Ontario Cancer Foundation Clinic, Victoria Hospital, London. It is proposed to interview about 35 patients with cancer at each site at each centre. In Toronto, two controls for each case will be selected at random from the same neighbourhood as the cases; in London, two controls for each case will be selected from female patients admitted to the hospital in which the clinic is located. Controls will be matched to the cases for age, within 5 years on either side of the case's age. Results are anticipted in the spring of 1979.

HISTORICAL-PROSPECTIVE STUDY OF THE LONG-TERM HEALTH EFFECTS OF EXPOSURE TO FIBROUS GLASS AND MINERAL WOOL

P. Enterline, University of Pittsburgh, Graduate School of Public Health, Dept. of Biostatistics, *4200 5th Ave., Pittsburgh, Pennsylvania* 15260 (D-IARC-79-1032)

Objective is to determine the cause-specific mortality experience of workers in the fibrous glass and mineral wool industries for periods up to 50 years after first exposure and relate this to duration and intensity of exposure and to the experience of the general population. Cohorts consisting of male workers with one year or more experience (exposure) in manufacturing between Jan. 4, 1945, and Dec. 31, 1963, will be developed. Vital status of this cohort will be determined as of Dec.31, 1973. Total cohort size is estimated to be about according to statistical analysis. The risk of death from selected causes will be established with a detailed examination of malignant neoplasms.

NATURAL HISTORY OF CARCINOMA IN SITU OF THE VULVA AND RESPONSE TO VARIOUS FORMS OF THERAPY

E. Friedrich, Medical College of Wisconsin, School of Medicine, Dept. of Gynecology & Obstetrics, *561 N. 15th St., Milwaukee, Wisconsin* 53233 (D-IARC-79-1076)

Carcinoma in situ of the vulva is a 'new' disease with a rapidly rising incidence curve. It occurs in young women and does not seem to be associated with invasive carcinoma of the vulva. Some cases have disappeared spontaneously. None have progressed to invasion under observation. The present study continues to find, record and observe cases of carcinoma in situ of the vulva, to gather data regarding race, age, parity, concomitant venereal disease, concomitant cancer of other location, occupation and - in some cases - response to various modes of therapy.

ASSOCIATION OF LUNG CANCER WITH CIGARETTE SMOKING

G.B. Gori, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Division of Cancer Cause & Prevention, *9000 Rockville Pike, Bethesda, Maryland* 20205 (D-IARC-79-849)

The objective of this retrospective study is to analyze differences in lung cancer incidence rates as a function of cigarette type and smoking habits among case-control groups in Austria, France, Germany, Italy, Scotland, Cuba and U.S.A. Interviews with hospital patients are conducted to obtain data regarding cigarette brands smoked, number of years using each brand, total number of years smoking, patterns of smoking, drinking habits and demographic data. Data for approximately 500 cases and 1,000 controls are collected annually in each participating country. Central data analyses are performed by Enviro Control, Inc., Rockville, Maryland 20852, U.S.A. (Dr. C.J. Lynch).

CASE-CONTROL STUDY OF OCCUPATION AND CANCER

T.M. Mack, University of Southern California, School of Medicine, Dept. of Pathology, *2025 Zonal Ave., Los Angeles, California* 90033 (D-IARC-79-730)

This study aims to explore differences between cases and controls in relation to occupation, exposure to chemicals, tobacco and alcohol use, diet, past history and family history. Cases are identified through the Cancer Surveillance Program at Los Angeles County/University of Southern California. Controls are selected on a nearest-neighbor basis, and matched by age, race, and sex. It is expected that, depending upon site, 200-600 cases and matched controls will be studied.

CHARACTERIZATION OF PROSTATIC CARCINOMA AMONG BLACKS

M.Y. Heshmat, Howard University, School of Medicine, Dept. of Preventive Medicine, *2400 6th St. N.W., Washington, District of Columbia* 20001 (D-IARC-79-763)

The aims of the study are to: 1) Compare the clinical features, plasma hormone (testosterone, oestrone,

oestradiol, and prolactin) levels, epidemiological factors, and tumor morphology in high-risk U.S. Blacks, 2) search for factors that may be associated with the development of prostate cancer in the U.S.A., 3) determine in postmortem material the frequency of incidental (non-invasive) carcinoma of the prostate in the two population groups and 4) study the relation between incidental carcinoma and non-neoplastic prostatic diseases and morphological changes in the liver, adrenal glands, breast, testis, and pituitary gland. All new untreated patients with prostate carcinoma are being admitted to the study. Blood samples are drawn from all male patients after admission to the urological services of the collaborating hospitals. All patients with histologically confirmed carcinoma of the prostate and all controls are interviewed about social and demographic factors, family history, food consumption habits, sexual history, past history of illnesses and operations, history of urogenital diseases, and use of contraceptives by sexual partners. Hospital control patients, age-matched, and free of clinically demonstrable neoplastic, urological, and endocrine conditions are used. In addition, the whole prostate gland is collected from consecutive necropsy cases of black men in Washington, D.C. Whole glands with attached seminal vesicles are accessioned, entered into a blind study, weighed, step-sectioned. From patients with the clinical diagnosis of carcinoma undergoing prostatic surgery, the histological grade of the tumor and other morphological features are correlated with clinical staging, hormonal studies, and epidemiological data. As of January 1978, 170 American and 78 African matched pairs (cancer and control) had entered the study.

GENETIC STUDIES OF BREAST CANCER

D.E. Anderson, University of Texas, University of Texas System Cancer Center, M.D. Anderson Hospital & Tumor Inst., Dept. of Biology, *c/o Texas Medical Ctr., Houston, Texas* 77030 (D-IARC-79-1041)

The purpose of this study is to identify patients with hereditary types of breast cancer. Patients with family histories of the disease are selected for study; controls are selected from the same patient population but have family histories of neoplasms other than the breast. Both groups are studied simultaneously with similar methodological approaches. Questionnaires are used for eliciting family and medical histories; all reported tumor occurrences are verified by a medical, hospital, pathological and/or vital statistics report. Patients have been classified according to various criteria: age at clinical onset, single or multiple primaries, type of family history, and associated familial neoplasms. Such classifications have identified groups of patients' relatives with varying risks of developing the disease, ranging from the usual 2-fold level to much higher levels. High lifetime probabilities of 30 percent have been observed for the sisters and daughters of patients whose mothers also had breast cancer. The occurrence of breast cancer in two successive generations of daughters with high lifetime probabilities of developing the disease is strongly indicative of a hereditary type of breast cancer. The mechanism of gene action is unknown. One possibility being investigated is oestrogen metabolism. An assay has been developed for measuring oestrogen hydroxylase activity. Although activity has been detected in murine livers, no activity has been observed in human lymphocyte cultures or long-term human lymphoblast cultures or in human breast cancer cell lines. Blood cell antigen and enzyme markers are also being tested in breast cancer families and controls in an attempt to identify high-risk women. Of the markers tested, only the ABO blood type was found to be significantly associated with breast cancer. Type A was in excess and type O was deficient in unselected patients and patients from low-risk pedigrees compared with controls, and more so at older than younger ages.

EFFECT OF ETHNICITY ON THE CLINICAL BEHAVIOR OF BILATERAL BREAST CARCINOMA

G.M. Bordin, Mexico Tumor Registry & Hospital of Scripps Clinic, Dept. of Pathology, *La Jolla, California* 92037 (D-IARC-78-841)

The age at diagnosis, interval between first and second breast carcinoma, and clinical stage at diagnosis for first and second breast carcinomas in Non-Spanish-American Caucasian and Spanish-American women will be compared. Age comparisons will be made with a control group without bilateral breast carcinoma. Data came from a population-based tumour registry covering an area where there are high risk (Non-Spanish-American) and low risk (Spanish-American) groups for breast cancer. A first analysis has been completed. The survey continues.

EPIDEMIOLOGY OF HEPATOMA AND CHRONIC LIVER DISEASE IN RELATION TO HEPATITIS B INFECTIONS IN TAIWAN

R. Beasley, University of Washington, School of Public Health & Community Medicine, Dept. of Epidemiology, *4000 15th Ave. N.E., Seattle, Washington* 98105 (D-IARC-79-742)

In Taiwan, where alcohol abuse is rare, chronic liver disease accounts for approximately 25% of all adult male deaths. Approximately half of these deaths are attributed to hepatoma, most with underlying cirrhosis, the other half to cirrhosis without hepatoma. Acute and chronic hepatitis are also very common. There is a high degree of association between these conditions and the hepatitis B surface antigen (HBsAg): hepatoma 90%, cirrhosis 80%, chronic hepatitis 70%, acute hepatitis 60%. Approximately 10-20% of the general, apparently healthy population are HBsAg carriers. Although most carriers are asymptomatic, liver function studies are frequently abnormal. This study will identify approximately 1,000-2,000 apparently healthy HBsAg carrier males 40-59 years of age. These will be followed for at least five years to determine the frequency of morbidity and mortality from liver disease. The liver disease rates in these carriers will be compared with those of 9,000 to 18,000 non-HBsAg carriers selected from the same population. Familial aggregation of HBsAg and chronic liver disease is also under study.

MEDICAL SURVEILLANCE AND INTERVENTION - BLADDER CANCER

D.L. Bayliss, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Biometry Section, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (D-IARC-79-983)

As aromatic amines, specifically beta-napthylamine, benzidine, and di-chloro-benzidine, have been responsible for cancer of the bladder in up to 100 percent of workers, the continued and increasing use of such carcinogens, not only in dye and pigment production but also in pharmaceuticals, detergents, food colors and specialized chemicals, makes it imperative that surveillance should continue so that situations similar to the current bladder cancer epidemic in New Jersey be prevented. A cooperative agreement is being developed with the National Cancer Institute to place all such exposed workers under medical surveillance. This will include periodic examinations and constant follow-up to detect early changes consistent with the development of bladder cancer.

EPIDEMIOLOGY OF STOMACH CANCER AND NITRATES IN CHILE

R. Armijo, University of California, Los Angeles Campus, School of Public Health, Dept. of Epidemiology, *405 Hilgard Ave., Los Angeles, California* 90024 (D-IARC-79-720)

An initial study, already published, demonstrated a correlation between nitrate exposure and stomach cancer mortality in Chile. The proposed study is designed to meet three major objectives: (1) to determine whether a significant difference in exposure to variables indicating a high nitrate intake exists in Chile between two groups of stomach cancer patients and their ill and well controls; (2) to search for additional factors which might be of significance, other than the cumulative nitrate exposure demonstrated in our previous correlation study; (3) to determine whether a correlation exists between nitrate/nitrite exposure indicators and stomach cancer in low and high risk areas of Chile. In order to meet the objectives, a case-control and a nitrate ecology study are proposed, to be carried out concurrently during a 20-month period. In the case-control study, cases and hospital and neighbourhood controls will be interviewed. A questionnaire specially designed to record long-term data has been already pilot-tested. The analysis of combinations of ten varieties throughout life periods defined by residence landmarks will explore differences in patterns between cases and controls. The nitrate ecology study includes the collection of specimens to determine nitrate/nitrite content of urine and saliva of school children and in food specimens, both in high and low risk areas. Confirmation of the correlation study by these proposed studies will help to substantiate the role of N-nitroso compounds in man.

2.2136,

MORTALITY EXPERIENCE OF HOUSEHOLD CONTACTS OF ASBESTOS WORKERS

H.A. Anderson, New York University, Graduate School, Environmental Sciences Lab, *100 Washington Sq. E., New York, New York* 10003 (D-IARC-79-932)

From 1941 to 1945 men were employed in an asbestos products factory in an eastern U.S. city. Approximately 2,225 individuals lived in their households, at the time of employment. This group is being identified and will form a cohort for the prospective evaluation of their mortality experience 1946-1980. It is already known that household contact disease may occur ('conjugal' asbestos disease); this information will provide quantitative information concerning the extent of that risk. Moreover, while mesothelioma is known to occur among household contacts, the risk of other disease has not been investigated. It is expected to obtain information in this regard as well. In parallel clinical studies, over 700 family contacts have so far been examined; one-third have chest x-ray abnormalities consistent with asbestos exposure.

2.2137,

PREDICTION OF LUNG CANCER RATES BY SPUTUM CYTOLOGY

V.E. Archer, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

In assessing the lung cancer risk of a worker population, it is highly desirable to have an early prediction method so that excess risk can be detected early.

For new chemicals suspected of being pulmonary carcinogens, sputum cytology may reduce by half or more the time needed to determine the existence of risk, thus possibly saving many lives. Several sputum samples from about 15,000 uranium workers have been collected over a period of 18 years. Using Dr. Saccomanno's classification, the samples will be analyzed to show correlation with age, tobacco smoking and radiation exposure. Persons with various grades of atypia will be followed to see how their sputum changes over the years, and to determine subsequent lung cancer mortality associated with each class of atypia (up to 18 years). Multiple correlation analyses will be done (utilizing support from NCI). These analyses will permit assessment of the use of sputum cytology as a survey tool assessing the lung cancer risk of a population before lung cancer has appeared.

THE PHILADELPHIA PULMONARY NEOPLASM RESEARCH PROJECT

W. Weiss, Hahnemann Medical College & Hospital, School of Medicine, Dept. of Medicine, *235 N. 15th St., Philadelphia, Pennsylvania* 19102 (D-IARC-79-1029)

The objective of this study is to investigate the natural history of lung cancer in a population of male volunteers aged 45 and over. A total of 6,027 men were enrolled in a prospective study from December 1951 to December 1955 and followed with semiannual chest photofluorograms and symptom questionnaires for 10 years. Medical information on all illnesses and deaths was collected. Data were placed on computer tape by 1968 and the results have been under continual analysis. A total of 121 men developed lung cancer at a rate of 2.3/1,000 man-years. The risk increased with increasing age, was higher in non-whites than in whites, and bore a dose-response relationship to cigarette smoking. None of 830 non-smokers developed lung cancer. The dose-response relationship between smoking and lung cancer held true for adenocarcinoma as well as for squamous cell and small cell carcinoma, but the gradient was not as steep. The characteristics of 'early' lung cancer have been described. Screening contributed little to the survival rate. Survival factors have been described. Chronic cough was found to be an additional risk factor. During the occult phase of the lung cancer chronic cough and expectoration were found to increase prior to x-ray detection of the cancer compared with matched controls. Further analysis is continuing.

EPIDEMIOLOGIC CHARACTERISTICS OF PRE- AND POST-MENOPAUSAL BREAST CANCER PATIENTS

D.C. Daubner, Duke University, School of Medicine, Dept. of Community Health & Family Medicine, *Box 3711, Durham, North Carolina* 27710 (D-IARC-79-975)

The goal is to define the epidemiological characteristics of breast cancer in pre- and post-menopausal women and to relate these characteristics to the pathobiology of the tumour as manifested by oestradiol and progesterone receptors, histology and cellular ultrastructure. This case-control study concerns breast cancer patients undergoing surgery at university and community hospitals, surgical or medical patients not having breast or gynaecological surgery at the same hospitals, and subjects from the community. Data collection is by interview of all subjects and review of charts of hospital patients. Laboratory studies on tissue and serum from breast cancer patients will include quantitative oestrogen and progesterone receptor determinations, evaluation of histology and ultrastructure by a standardized protocol, and oestrogen and progesterone serum determinations. Statistical analyses will estimate the relative strength of association between breast cancer and pre- and post-menopausal women and such factors as age at menarche, age at first delivery, obesity, and family history of breast cancer. Associations between risk factors and tumour cell biology and morphology will be sought by comparing the laboratory results in women with and without single or multiple risk factors.

TRENDS IN MORBIDITY AND MORTALITY OF UTERINE CANCER IN RELATION TO MASS CYTOLOGICAL SCREENING

W.M. Christopherson, University of Louisville, School of Medicine, Dept. of Pathology, *101 W. Chestnut, Louisville, Kentucky* 40202 (D-IARC-79-817)

A population-based registry of all uterine tumors in Jefferson County, Kentucky, has been maintained since 1953. Jefferson County has had mass cytological screening since 1956 and by as early as 1967 over 90% of the population had been screened. Morbidity and mortality trends as well as patient survival and a record of histological type have been monitored. Over the period of the study mortality from cervix cancer has decreased significantly when compared to mortality trends in United Kingdom and Ireland and in Denmark. The study continues.

INVESTIGATION OF EXCESS GALLBLADDER CANCER AMONG SPANISH WOMEN IN NEW MEXICO, WITH SPECIAL EMPHASIS ON RIO ARRIBA COUNTY

R.W. Buechley, University of New Mexico, School of Medicine, Epidemiology Section, *University Hill N.E., Albuquerque, New Mexico* 87131 (D-IARC-79-909)

Mason and McKay's Atlas of Cancer in the USA reports a significant excess of liver and bile duct cancer in Rio Arriba County females from 1950 to 1969. Cursory examination of 1950-1966 Rio Arriba death certificates reveals a primitive pattern of causes of death, mostly communicable diseases and accidents. New Mexico Tumor Registry records from 1969-1975 show elevated morbidity rates for gallbladder cancer in Rio Arriba County, with rates for Spanish American females estimated to be 15 times those for US females. (In New Mexico the term 'Spanish American' distinguishes persons of Spanish ancestry settling before 1845 from recent Mexican migrants.) Extraction of 1957-1969 death records and of 1969-1975 morbidity records indicates that these women are of non-migrant families, possibly highly inbred. Historical considerations lead to the hypothesis that they descended from Plains Indians settled in the county between 1780 and 1830, after De Anza defeated the raiding Comanches. Cregan and Fraumeni have found American Indian populations to be at high risk for gallbladder cancer. New Mexico age-adjusted incidence rates for 1969-1975 are 5.1 for male Indians and 21.1 for female Indians. Two sisters and a mother and daughter have been among the Rio Arriba gallbladder cancer decedents. For no other site of cancer have any relatives been found. This strengthens the plausibility of a familial or genetic explanation. It is proposed to test hypotheses of Indian ancestry and of familial aggregation by blood typing, genealogy, and other appropriate methods.

2.2144,

EPIDEMIOLOGICAL AND INDUSTRIAL HYGIENE STUDY OF ALUMINUM REDUCTION WORKERS

D.P. Brown, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Biometry Section, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (D-IARC-79-984)

Workers in aluminum reduction industry are exposed to a variety of substances, e.g., hydrogen fluoride fumes, dust, carbon monoxide and coal tar pitch volatiles (CTPV) such as benz(a)pyrene. Coal tar pitch volatiles are released in the anode preparation area in plants using pre-baked anodes and in the pot lines where Soderberg self-baking cells are used. The release of CTPV is thought to be temperature dependent. Sufficiently high temperatures are reached in both anode preparation and electrolysis of aluminum to achieve the release of such materials. Industrial hygiene surveys of the aluminum reduction industry have revealed levels of CTPV well above the current occupational health standard of 0.2 milligram per cubic meter (mg/m3) by the benzene soluble fraction method. A variety of studies have been carried out to describe the cancer mortality experience of workers in aluminum reduction facilities. Milham (1976) has reported an increase in proportionate mortality from total cancer, cancer of the pancreas, cancer of the respiratory system, and malignant lymphomas among aluminum workers in Washington State. In a study by Tabershaw/Cooper, cause-specific standard mortality ratios, calculated for subgroups in the study population defined by major process, showed a positive association between employment as a potroom worker and lung cancer, leukemia, and lymphoma. In order to more fully define the specific cancer risk within the potrooms, a retrospective case control study is planned on aluminum workers exposed to CTPV. Industrial hygienists will assist in classifying job categories and in verifying related industrial hygiene data.

CANCER A[illegible]NG CHILDREN OF NURSE ANESTHETISTS

A.F. Kantor, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510 (D-IARC-79-756)

This study will investigate the cancer experience of nurse anesthetists and their children. A retrospective case-control approach will be employed using an employment history for both nurses and controls. Results will be compared with Connecticut Tumor Registry data on childhood cancer experience in order to test the hypothesis that inhalation of anesthetic gases by pregnant operating room personnel increases the risk of cancer in their offspring.

2.2148,

CANCER RISK AND CYCLOPHOSPHAMIDE USE

A.F. Kantor, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510 (D-IARC-79-755)

This study tests the hypothesis that cyclophosphamide use is related to urinary bladder cancer and/or other neoplasms, particularly among lymphoma patients receiving the drug for extended time periods. Two sites of primary cancer (Hodgkin's disease and multiple myeloma) will be examined. Cases diagnosed between 1960 and 1970 and followed through 1973 will be examined. Analysis will review observed and expected numbers of second cancer, taking treatment, age, sex, and stage of disease into account.

SURVEY OF EBV AND BURKITT'S LYMPHOMA IN AN ISOLATED AREA OF PERU ENDEMIC FOR NON-P. FALCIPARUM MALARIA

P.M. Feorino, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, Viral Oncology Branch, *1600 Clifton Rd. N.E., Atlanta, Georgia* 30333 (D-IARC-78-654)

A primitive isolated population in the Peruvian Amazon Jungle has been studied for the presence of antibodies to P. falciparum, P. malariae and EBV. No antibodies to P. falciparum were found even though the tribe lived in an area highly endemic for malaria. Almost all individuals studied had antibodies to EBV and P. malariae; these antibodies were acquired at an early age and maintained at a high level. A preliminary investigation shows little or no Burkitt's lymphoma in this area. This tribe affords an unusual opportunity to study Burkitt's lymphoma, EBV, P. malariae and P. falciparum.

EPIDEMIOLOGY OF CANCER IN FAMILIES WITH IMMUNODEFICIENCY

J.H. Kersey, University of Minnesota, Minneapolis Campus, School of Medicine, Dept. of Laboratory Medicine & Pathology, *1305 Mayo, Minneapolis, Minnesota* 55455 (D-IARC-79-886)

In connection with work begun under the auspices of the Immunodeficiency Cancer Registry, the association between immunodeficiency diseases and cancer is being investigated. This study focuses on the Wiskott-Aldrich Syndrome and will utilize both epidemiological and laboratory methods to achieve the following goals: (1) to validate preliminary evidence collected by the Immunodeficiency Cancer Registry which suggests that there is an increased risk of cancer in males affected with Wiskott-Aldrich Syndrome; (2) to determine if this apparent increased risk extends to female carriers of Wiskott-Aldrich Syndrome; (3) to evaluate differences found in cancer frequencies for the Wiskott-Aldrich Syndrome families studied. Families of over 150 Wiskott-Aldrich Syndrome cases in the United States and Canada are being contacted and, with the cooperation of various family members, pedigrees are being constructed. Because Wiskott-Aldrich Syndrome is an x-linked recessive disorder, female carriers of the gene(s) for this disorder can be defined, within a probability range, when the probands are tagged through pedigree analysis and medical records verification. A study population of carriers will be developed from pedigree information; Various relatives will be systematically selected for a comparison of the lifetime prevalence of cancer among carriers (cases) and non-carriers (controls). Medical records and death certificates will be used to verify the occurrence of malignancy.

AGE-DISTRIBUTION OF LUNG CANCER IN PATIENTS AT VETERANS ADMINISTRATION HOSPITAL - HINES, ILLINOIS

H.T. Langston, Northwestern University, Chicago Campus, School of Medicine, *303 E. Chicago Ave., Chicago, Illinois* 60611 (D-IARC-79-813)

The age-distribution study previously reported now spans the 35 years between 1939 and 1973. As anticipated, the number of cancers contributed by the generation born between 1890 and 1900 fell off in the last quinquennial period of 1969 to 1973. This is now, after all, an aging cohort. There were 350 patients in the younger age groups (35-59 years) in the 1939 to 1943 period (90 percent of the total) and only 464 patients in the same age range in the 1969-1973 period (56 percent of the total). This supports the view that the younger cohorts are not fully replacing the older and aging generations. The total number of cases in this hospital during the 1969 to 1973 period did not increase.

EPIDEMIOLOGICAL STUDY OF DIETARY COMPONENTS AND CANCER DEVELOPMENT

L.N. Kolonel, University of Hawaii System, Manoa Campus, School of Public Health, Dept. of Biomedical Sciences, *Spalding Hall, Room 255, Honolulu, Hawaii* 96822 (D-IARC-79-788)

This study correlates group-average dietary intake data, acquired over a three-year period on a representative sample of 6,000 Oahu residents of Caucasian, Japanese, Chinese, Filipino and Hawaiian ancestry, with the race-, age- and sex-specific incidence rates for various sites of cancer. Dietary information is obtained by personal interview, using a pre-tested questionnaire and color photographs to help establish quantitative intake. To obtain a representative sample of the population, the study takes advantage of the health surveillance program of the Hawaii Dept. of Health, which each year identifies a cluster sample of 5,000 households throughout the state. Race-, sex-and age-specific incidence rates for cancer are provided by the Hawaii Tumor Registry.

ECOLOGICAL, STATISTICAL, ETHOLOGICAL AND RELATED BIOLOGICAL STUDIES ON AIR POLLUTION, SMOKING AND OTHER ENVIRONMENTAL VARIABLES (ABBREV)

R.J. Hickey, University of Pennsylvania, Wharton School of Finance & Commerce, Dept. of Statistics, *34th & Spruce Sts., Philadelphia, Pennsylvania* 19104 (D-IARC-79-1024)

Statistical and other studies are being conducted to test a four-part hypothesis that: (1) Among common air pollutant chemicals there are some that are mutagenically or otherwise hazardous to health; (2) such chemicals accelerate development of and increase risk of occurrence and mortality from chronic diseases of aging (e.g., cancer, heart disease), and also alter intergenerational DNA leading to birth defects and their consequences, in proportion to exposure; (3) chronic disease risk and resultant mortality are influenced significantly by individual genetic/constitutional characteristics; and (4) these individual characteristics also significantly influence certain behavioral physiological characteristics, such as tobacco smoking and coffee drinking. Three subsidiary hypotheses are that (5) smoking is, for many, symptomatic of physiological deficiencies that nicotine tends to alleviate, with smoking functioning partly as an example of behavioral regulation of physiological homeostasis, (6) viruses can also function mutagenically, along with certain environmental pollutant chemicals, leading to accumulation of somatic mutations, and (7) recent urban mortality rate data are more strongly correlated with air pollution levels of, say, 10 years ago than with recent levels. The basis for (7) may be a result of cumulative, and possibly multiplicative (cf. Orgel's theory), long-term effects of cell alterations inflicted by pollutant chemicals and other factors, including viruses. Methods of multivariate statistical analysis are used in these multi-regional, multi-environmental variable studies, especially an optimal subset selection (algorithm) modification of multiple regression analysis. Data used are human mortality rates for all cancers, cancers of various sites, and leukaemia, along with other chronic diseases (e.g., heart disease) for individual metropolitan populations, and environmental chemical concentration data and other environmental variable data.

HUMAN RADIATION CARCINOGENESIS STUDY

L.H. Hempelmann, University of Rochester, School of Medicine & Dentistry, Dept. of Radiology, *601 Elmwood Ave., Rochester, New York* 14627 (D-IARC-79-964)

For the past 20 years, we have been following the health status of the following three populations of persons given radiation treatment for benign conditions many years before: (1) 2,872 persons given x-ray treatments in infancy for thymic enlargement and their 5,055 untreated siblings; (2) 606 women given x-ray treatment for acute postpartum mastitis controlled by 554 untreated sisters and by 539 women with a history of acute postpartum mastitis not treated with x-ray treatments and 206 of their untreated siblings; and (3) 971 persons given x-ray treatments to the head during childhood for lymphoid hyperplasia of the nasopharynx, 417 persons treated with intranasal radium capsules for the same condition and the 2,751 non-irradiated siblings of the irradiated subjects. In the thymus-irradiated series (1), an increased incidence of neoplasms and of illnesses with autoimmune features was observed as compared to that seen in the non-irradiated siblings and in the general population. Only thyroid neoplasms occurred in sufficient numbers to permit analysis of incidence as a function of dose and other factors. Radiation-induced thyroid cancer shows a linear dose response. Jews and females have an increased risk of developing thyroid cancer. In the breast-irradiated women (2), the incidence of breast cancer is increased over that in the controls beginning 15 years post-exposure and shows a dose response with an apparent peak in the 400-599 r (air) category. In 1961, the head-irradiated population (3) was shown to have an increased incidence of radiation-induced neoplasms. They are being resurveyed at the present time.

REGISTRY FOR RESEARCH INTO HORMONAL TRANSPLACENTAL CARCINOGENESIS

A.L. Herbst, University of Chicago, School of Medicine, Dept. of Obstetrics & Gynecology, *5601 S. Ellis Ave., Chicago, Illinois* 60637 (D-IARC-79-807)

The Registry has been established to collect clinical, pathological and epidemiological data on cases of clear cell adenocarcinoma of the genital tract in women born after 1940 regardless of whether or not the patient has a history of prenatal exposure to hormones, and all cases of genital cancer (vulva, vagina, cervix, endometrium, tube, ovary) in any female with a reasonable possibility of exposure in utero to any exogenous sex hormones, including steroidal oestrogens and progestins. Material for review is sought from all such cases occurring in the United States or other countries. Cases may be reported to: Registry for Research on Hormonal Transplacental Carcinogenesis, MARP 303, 5841 South Maryland Ave., Chicago, IL 60637. Pathological studies are conducted at Massachusetts General Hospital in Boston with Drs. Scully, Robboy and Welch as collaborators.

DEVELOPMENT OF STATISTICAL AND COMPUTER METHODS FOR THE ANALYSIS OF INCIDENCE AND MORTALITY DATA

J.A. Lee, University of Washington, School of Public Health & Community Medicine, Dept. of Epidemiology, *4000 15th Ave. N.E., Seattle, Washington* 98105 (D-IARC-79-1067)

The aim of this study is to develop and make available methods for the dissection of generation, age, and time period effects from the matrices of data provided by cancer registries and vital statistical systems on the occurrence of human cancer. A standard Fortran program (which we would be happy to share) has been prepared which provides at small cost a printout of a very large number of rates and other indices from a set of deaths or cases in five-year age groups and five-year time periods and the appropriate population estimates. It is hoped to develop this to provide estimates of the deeper regularities, e.g., the influence of age or generation differences if historical changes did not occur. Analysis of data sets has shown that inter-cohort differences may be due to historical variations in the changes of rates with age as well as due to generation differences. Studies are in progress on malignant melanoma, cancer of the breast, lung and large bowel, and on Hodgkin's disease. An initial paper on breast cancer has been published (JNCI, March 1979).

SURVEILLANCE FOR DRUGS THAT MAY BE CARCINOGENIC

G.D. Friedman, Kaiser Permanente Medical Care Program, Dept. of Medical Methods Research, *3700 Broadway, Oakland, California* 94611 (D-IARC-79-741)

The objective is to evaluate medicaments for possible carcinogenic effects. To seek hypotheses, 150,000 persons will be classified according to use and non-use of various medicaments by means of computer-stored records collected from 1969-1973 by the San Francisco Kaiser-Permanente Clinic (1.3 million prescriptions for 3,400 drugs). The development of various kinds of cancer will be followed up by surveillance of hospital records. Drug-cancer associations found would be subjected to further study. More detailed evaluation of hypotheses would be by case-control studies using the Kaiser-Permanente records, with attention to potential confounding variables.

STUDY OF THE ROLE OF DIET IN THE ETIOLOGY OF COLON CANCER

W.H. Gullen, Medical College of Georgia, School of Medicine, Dept. of Family Practice, *1459 Gwinnett St., Augusta, Georgia* 30902 (D-IARC-79-783)

Several studies have implicated dietary factors (especially animal proteins, cholesterol and refined carbohydrates) in the aetiology of colon cancer. This case-control study is being conducted in 9 cooperating hospitals in the Atlanta, Georgia area. Suspect cases of colon cancer are matched with controls (age, race, sex) and each subject is interviewed regarding past diet. Subjects are followed until definitive diagnosis. Controls are subsequently admitted inpatients with other conditions (with certain exclusions). Matching is by age (within an arbitrary number of years), sex, race and hospital. A number of other factors are investigated (e.g., use of medications). Special emphasis is placed on southern U.S. Blacks since their colon cancer incidence is less than in Whites and northern Blacks.

EPIDEMIOLOGICAL STUDIES OF CANCER IN LOUISIANA

M.S. Gottlieb, Tulane University of Louisiana, School of Medicine, Dept. of Medicine, *1430 Tulane Ave., New Orleans, Louisiana* 70112 (D-IARC-79-823)

Death certificates for cancer of the lung, nasopharynx, pancreas and bladder will be identified for selected Louisiana parishes for the years 1960-1975. Controls will be matched by parish of residence, year of death, age (within 2 years), sex and race. The frequency of occurrence of names attributable to groups with a common heritage will also be compared, as will relationship of residence at death and distance from selected industries, and water source. The objective is to determine single or multiple factors which can be identified as associated with a greater risk in cases compared with controls. This will form the basis of subsequent additional observational studies. Sub-studies on populations exposed to unique substances are included.

2.2165,

EPIDEMIOLOGY OF UTERINE CERVIX CANCER IN AN AREA OF LOW INCIDENCE

J.L. Lyon, Utah Higher Education System, University of Utah, School of Medicine, Dept. of Family & Community Medicine, *1400 E. 2nd S., Salt Lake City, Utah* 84112 (D-IARC-79-1058)

Over the last 20 years the State of Utah has had 25% lower mortality than the U.S.A. as a whole from cancer of the uterine cervix. Members of the church of Jesus Christ of Latter-Day Saints (Mormons) have rates of cervical cancer 50% below those of the non-Mormons in Utah. The Mormon population also has a higher fertility rate and age of marriage than non-Mormons. A case-control study to investigate the aetiology of cervical cancer in both Mormons and Non-Mormons residing in the State of Utah is proposed. Cases will be identified through a population-based cancer registry, and controls matched for age and county of residence will be identified from the general population. Cases and controls will be interviewed concerning age when first married, first pregnancy, commencement of sexual intercourse, divorce, number of sexual partners, and venereal disease exposure.

SUPPORTED BY (No Supporting Organization Reported) funds n.a.

2.2166,

DIET AND COLON CANCER IN A LOW RISK POPULATION

J.L. Lyon, Utah Higher Education System, University of Utah, School of Medicine, Dept. of Family & Community Medicine, *1400 E. 2nd S., Salt Lake City, Utah* 84112 (D-IARC-79-1059)

The incidence of colon cancer in Utah is 30 to 35% below USA rates. Important risk differences by place of residence and religion are also present in the Utah population. A case-control study to explore the effect of diet on these unusual risk factors is under way. Cases of colon cancer are identified and a population control chosen. Interviews obtain extensive dietary information. Dietary items are also analyzed by their components for elements associated with colon cancer such as high fat intake.

LATE EFFECTS OF CANCER TREATMENT IN CHILDREN INCLUDING SECOND MALIGNANT NEOPLASMS - CHILDREN'S INTERNATIONAL CANCER INVENTORY

A.T. Meadows, University of Pennsylvania, School of Medicine, Dept. of Pediatrics/Oncology, *36th & Hamilton Walk, Philadelphia, Pennsylvania* 19174 (D-IARC-79-1026)

As treatment for childhood cancer was becoming more successful and rate of survival was improving, an interest developed in studying these children for late effects of radiation and chemotherapy to organic systems. Also of interest was the rate of second tumors in these survivors, whether treatment-related or not. Begun in 1972 at three pilot institutions, the study has been expanded to include children with cancer at 11 institutions, particularly with reference to: (1) Second malignant neoplasms, (2) the offspring of survivors, (3) unusual childhood tumors, (4) congenital anomalies in patients, (5) data regarding siblings and other family members for cancer and congenital defects. The Children's International Cancer Inventory will collect registration data on all new patients seen at each of the cooperating institutions and these will be followed prospectively. In addition, retrospective studies will be begun to study 1-5 above. The second neoplasm study is well under way, and we have collected 137 cases up to 1977.

SUPPORTED BY (No Supporting Organization Reported) funds n.a.

OHIO CENTRAL DATA BASE FOR CHILDHOOD CANCER

W.A. Newton, Ohio State University, Columbus Campus, Childrens Hospital, *561 S. 17th St., Livingston Pike, Columbus, Ohio* 43205 (D-IARC-79-1016)

The objective is to provide baseline information on demographic patterns for cancer morbidity and mortality in Ohio children. This includes case-finding information regarding type of cancer by age, race, sex, place of residence, staging at initial diagnosis and institution of initial diagnosis. Abstracts are being prepared on hospital discharge of all newly diag-

nosed children with cancer beginning January 1975 from all the major treatment centers for children in Ohio. These abstracts utilize forms currently in use in a broader data collection program, the Children's Hospital Automated Medical Program (CHAMP), a medical research computer center located in Children's Hospital, Columbus, Ohio. In addition, an epidemiological questionnaire to be completed by parents is also being collected. This includes general questions on family history, including cancer in relatives and malformations, with additional specific information on patients with leukemia, brain tumors, Wilms' tumor and malignant lymphoma.

2.2169,
INTERNATIONAL CASE-CONTROL STUDY OF BLADDER CANCER
A.S. Morrison, Harvard University, Boston Campus, School of Public Health, Dept. of Epidemiology, *55 Shattuck St., Boston, Massachusetts* 02115 (D-IARC-79-870)
The objectives of this study are: (1) To estimate the risk ratio and attributable risk of developing lower urinary tract cancer (bladder cancer) associated with coffee drinking in geographic areas which vary with respect to exposure rates and ethnic composition; (2) to estimate the risk ratio and attributable risk of bladder cancer associated with drinking other beverages, smoking, participating in certain occupations, use of analgesics, and ingestion of artificial sweeteners and bracken fern. In Boston (Massachusetts), Manchester (United Kingdom) and Nagoya (Japan), all new cases of bladder cancer in geographically defined populations will be ascertained over two to three year periods. Controls will be selected from the general population. Exposure information is to be collected by home interview.

2.2173,
MORTALITY IN THE CONNECTICUT TUMOR REGISTRY INCIDENCE FILE
L.D. Marrett, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510 (D-IARC-78-890)
This study examines the relationship between cancer incidence and cancer mortality to determine whether trends in mortality reflect equivalent trends in incidence, or indicate changing patterns in certification of cause of death or case-fatality rates. Using Connecticut Tumor Registry data, the site-, age-, sex-specific mortality experience of incident cancer cases can be described in terms of coded cause of death; it is possible, therefore, to characterize those cases who die of some cause other than cancer in terms of demographic and disease-related variables. To date deaths occurring between 1950 and 1988 amongst incident cases of cancer of the lung and bladder have been analyzed in this manner.
SUPPORTED BY (No Supporting Organization Reported) funds n.a.

2.2174,
PROPORTIONAL OCCUPATIONAL ANALYSIS USING DEATH CERTIFICATE DATA
L.D. Marrett, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510 (D-IARC-79-758)
Occupational data for a random sample of 8,000 Connecticut adults who died between 1959 and 1961 have been collected and coded. Occupation, industry, birthplace and cause of death for this general population sample will be compared with those of deceased Connecticut Tumor Registry incidence cancer cases. Such analyses will control for sex, age at death, and socioeconomic status. These data are currently being used in the studies of occupational factors in urinary bladder cancer and chronic leukaemia in Connecticut. It is hoped that the results of these and similar studies on other cancer sites will suggest new hypotheses regarding associations between occupational exposures and subsequent cancer experience.

2.2175,
A DEMOGRAPHIC ANALYSIS OF MULTIPLE CAUSES OF DEATH
K.G. Manton, Duke University, Center for Demographic Studies, *Durham, North Carolina* 27706 (D-IARC-78-798)
The study has the general purpose of examining linkages among disease entities within various demographic (age, sex, race) groups and the changes of these linkages over time. In particular, an analysis will be made of the demographic characteristics of persons who died from various types of cancer. Once the descriptive phase of the study is complete our attention turns to deriving mathematical models of cancer incidence, growth and mortality, which will be then used in studies of cancer latency. The goal of the project is to develop biologically plausible models of cancer growth which are consistent with the frequency of cancer at death. Attention will also be given to the possibility of developing similiar models for other disease entities.
SUPPORTED BY (No Supporting Organization Reported) funds n.a.

2.2176,
EPIDEMIOLOGICAL STUDY OF ENDOMETRIAL CANCER
R.S. Paffenbarger, University of California, Berkeley Campus, School of Public Health, Dept. of Biomedical & Environmental Health Sciences, *Berkeley, California* 94720 (D-IARC-79-713)
Endometrial cancer incidence in northern California Caucasian women had been rising steadily over the last decade, at a rate considerably greater than chance expectation: hormonal influence from prior reproductive events and female hormones taken therapeutically (or prophylactically) are suspected causes. Using case-control methods, it is intended to study childbearing practices (e.g., age at first birth, child spacing, number of children, infertility, etc.), together with the use of post-menopausal and other hormones, of 900 women who develop endometrial cancer and of appropriate control women who do not. Information will be collected by hospital or home interview from study subjects living in five San Francisco Bay Area counties. We anticipate being able to identify the kinds of pregnancy and childbearing experience that distinguish those women who are at greatest risk of subsequent endometrial cancer. Relative risks will be computed for women who chose to remain childless, for those who deliberately decided on late childbearing, and for those who were unable to conceive.

DEFINITION OF EPIDEMIOLOGICAL CHARACTERISTICS OF PRE- AND POST-MENOPAUSAL BREAST CANCER
R.S. Paffenbarger, University of California, Berkeley Campus, School of Public Health, Dept. of Biomedical & Environmental Health Sciences, *Berkeley, California* 94720 (D-IARC-79-711)
Using case-control methods, interviews of Caucasian, Negro, and Oriental women in the San Francisco Bay Area, totalling over 2,500 breast cancer patients and 5,000 controls, will be conducted in the three-year period beginning July 1, 1976. Characteristics receiving special attention include age, catamenial and childbearing events, indicators of early fertility, exogenous hormone and drug use, sociocultural factors, family history of cancer, radiation exposure, truncated dietary histories, and various physical measurements. Extent of disease (staging), histological diagnoses, and survival are established. Associations between epidemiological characteristics and breast cancer (pre-menopausal vs. post-menopausal) will be sought.

2.2178,
REPRODUCTIVE CAPACITY AND BREAST OR OVARY CANCER RISK
R.S. Paffenbarger, University of California, Berkeley Campus, School of Public Health, Dept. of Biomedical & Environmental Health Sciences, *Berkeley, California* 94720 (D-IARC-79-712)
Recent work by MacMahon et al. showed that increased risk of breast cancer in women with fewer children may be due to late age at first childbirth. Similarly, Joly et al. have shown that increased risk of ovary cancer may be due to delay in first pregnancy. A differing view could be that late childbirth or late pregnancy and carcinogenesis relate to a common hormonal aetiology. A special contribution of the study (2,250 cases of breast cancer and 900 cases of ovary cancer) is to determine whether increased cancer risk differs according to whether the late childbirth or pregnancy is due to lower fertility or to a voluntary delay of pregnancy. Since the hormonal pattern resulting from early pregnancy may not be the same as that associated with basic reproductive capacity, this case-control study, with emphasis on reasons for early or late pregnancy, will assess need for specific hormonal studies of breast and ovary cancer risk.

2.2180,
FIBROCYSTIC DISEASE OF THE FEMALE BREAST AND ITS RELATIONSHIP TO MAMMARY CARCINOMA
D.L. Page, Vanderbilt University, School of Medicine, Dept. of Pathology, *21st Ave. S. & Garland, Nashville, Tennessee* 37232 (D-IARC-78-883)
The investigators are assembling, reviewing and classifying slides from breast biopsies of 4,000 women performed 10 or more years ago and diagnosed as benign breast disease at that time. All

material is being classified as to the component parts of cystic disease present, using modification of the generally accepted categories of histological alteration included under the term 'cystic disease'. Correlation studies between the subsequent development of carconoma, the component types of cystic disease (including papillary and lobular peripheral lesions) and various historical features of each patient will be undertaken. The final goal of this study will be to assign a predictive index to types of fibrocystic disease, permitting assignment of relative risk to individual patients for the likelihood of the development of carcinoma. Results to date after analysis of 1,000 women with biopsies perrmformed eighteen or more years ago show that women lacking epithelial proliferative changes have the same cancer risk as the non-biopsied population-at-large.

MORTALITY STUDIES IN RELATION TO OCCUPATIONAL EXPOSURE TO CHEMICALS

M.G. Ott, Dow Chemical Co., *220 Dow Ctr., Midland, Michigan* 48640 (D-IARC-79-883)

These studies are part of a continuing program to evaluate the relationships between occupational exposure to chemicals and cause-specific mortality. A retrospective cohort approach is followed, with potential exposure classified on the basis of industrial hygiene surveys and employee work histories. The following units are included in current studies: styrene-based products (manufacturing and research), production of nitrogenous organic dyes, a fiber production process using methylene chloride as a solvent, and a manufacturing unit with diverse chemical operations.

FOLLOW-UP OF U.S. ARMY WORLD WAR II VETERANS WITH CERTAIN CONDITIONS POSSIBLY PREDISPOSING TO CANCER

C.D. Robinette, National Academy of Sciences, Medical Follow Up Agency, *2101 Constitution Ave. N.W., Washington, District of Columbia* 20037 (D-IARC-79-772)

About 16,000 men who served in the U.S. Army in World War II and who were admitted to hospital with certain illnesses or medical conditions while in service are being traced to determine whether they have elevated mortality from cancer, or from other causes. Conditions being studied are nephrectomy, splenectomy, orchidopexy, bronchial asthma and hay fever, and chronic alcoholism. Controls are about 16,000 men admitted to hospital for contused wounds or nasopharyngitis. The period of follow-up extends from January 1946 to December 1974.

EPIDEMIOLOGICAL AND GENETIC STUDIES IN PROSTATIC CANCER

I.D. Rotkin, University of Illinois, Medical Center at Chicago, Abraham Lincoln School of Medicine, Dept. of Preventive Medicine & Community Health, *1853 W. Polk St., Box 6998, Chicago, Illinois* 60680 (D-IARC-79-809)

This program has assembled and is studying known and suspected epidemiological and genetic events, factors and attributes possibly related to risk of prostatic carcinoma, sorting out those which may directly or indirectly influence onset of the lesion. Additional objectives are to explore strategies for prevention and early detection of this prevalent cancer, to identify individuals at increased risk, to provide hypotheses useful in repeat studies and prospective designs, to establish a rationale for the natural history of prostatic cancer, to structure models for oncogenesis in the human prostate, and to develop an information base for clinical and population screening programs which may contribute to reduction of morbidity and mortality rates from this disease in the population. The research design is a collaborative retrospective matched-pair case-control study designed and directed by Dr. I.D. Rotkin at the University of Illinois College of Medicine with sampling at 3 cooperating institutions in 2 widely separated metropolitan areas, the West Side Veterans Administration Hospital in Chicago, Northwestern University Medical School in Chicago and the Kaiser-Permanente Medical Center in Los Angeles, providing multiple-hospital access to large populations of prostatic cancer patients and opportunity for reproducibility comparisons by institutions, by geography, by race and by socioeconomic levels; and also full studies of 500 securely diagnosed patients against 500 cancer- and BPH-free controls. Epidemiological information is obtained with interviewer-administered questionnaires and related instruments inquiring into behavioral, environmental, sociocultural, sexual, physical, psychological and clinical factors associated with risk of this carcinoma. Familial studies are conducted into 3 generations of each kinship, with patients and controls as probands, in searching for genetic influence upon initiation of oncogenesis.

PROSPECTIVE FIELD STUDY - HORMONE ASSAYS AS A PREDICTOR OF HIGH BREAST CANCER RISKS

D. Rose, University of Wisconsin, Madison Campus, Wisconsin Clinical Cancer Center, Dept. of Human Oncology, *1300 University Ave., Madison, Wisconsin* 53706 (D-IARC-79-1073)

A breast cancer detection clinic, located at the Milwaukee County Hospital, under the direction of Dr. John Milbrath of the Medical College of Wisconsin, is one of 29 demonstration projects of the American Cancer Society and the National Cancer Institute. Each center is charged with screening 10,000 asymptomatic patients, aged 35 to 75, by physical examination, mammography and thermography at yearly intervals for a total of five years. Each of the 10,000 individuals will be followed for five years. In July 1974, the Medical College of Wisconsin and the Wisconsin Clinical Cancer Center jointly undertook an endocrinological study of women taking part in the breast cancer screening programme. The principal objective is to examine the claim by Bulbrook, Hayward, and Spicer that women with a high risk of developing breast cancer can be identified by their subnormal excretion of androgen metabolites in the urine. To this end, the plasma and urinary androgen levels of those patients found to have breast cancer by the screening procedure are being compared with those of closely matched controls. In addition, follow-up of the total population of screened women will determine whether or not those with low androgen metabolite excretions are at an increased risk of breast cancer. The occurrence of factors recognized as risk factors for breast cancer will also be determined by the use of a questionnaire, and the responses correlated with the steroid data. In this way, it may be possible to develop a combined epidemiological-endocrine discriminant to ensure greater selectivity of women at high breast cancer risk.

FACTORS ASSOCIATED WITH GEOGRAPHICAL DIFFERENCES IN AGE-SPECIFIC CHRONIC DISEASE DEATH RATES, INCLUDING VARIOUS SITES OF CANCER

H.I. Sauer, University of Missouri, Columbia Campus, School of Medicine, Dept. of Community & Family Medicine, *M228 Medical Sciences, Columbia, Missouri* 65201 (D-IARC-79-893)

Marked race-sex-specific differences have been demonstrated in the risk of dying at ages 45-54, 55-64, 65-74, for counties and the 510 state economic areas within the United States, as well as between portions of other countries. The geographical patterns are quite similar for various time periods, from 1949-1951 to 1968-1972. Mortality patterns for malignant neoplasms (all sites) and for lung cancer and cancer of the pancreas are correlated with death rates for the cardiovascular diseases (P less than 0.01). These patterns suggest that geographical differences in the patterns of cigarette smoking and other environmental variables may be responsible. Various techniques are being used to identify and adjust for possible shortcomings in the vital statistics data for epidemiological studies of this type. Many risk factors and suspected risk factors have been found to have statistically significant associations with the risk of dying. Several approaches are being used to test hypotheses as to the factors which are causally associated with these differences in the risk of dying and in the risk of cancer and other chronic diseases. Death rates for 1973-1976 are being compared with rates for earlier time periods, and are being used for testing the strength of various factors.

2.2186,

RETROSPECTIVE STUDY OF PESTICIDE USAGE AS A FACTOR IN CANCER MORTALITY

E.P. Savage, Colorado State University, Inst. of Rural Environmental Health, Epidemiologic Pesticide Study Center, *Spruce Hall, Fort Collins, Colorado* 80523 (D-IARC-79-749)

Some pesticides are suspected of causing cancer in laboratory animals. The objective of this study is to epidemiologically investigate pesticide usage as a factor in cancer mortality. After collecting historical pesticide usage data for Colorado and neighboring states, it is planned to stratify geographical areas within the states by the degree of pesticide usage. In this retrospective study, mortality risks for different levels of usage will be calculated for individual sites of cancer.

TRACE ELEMENTS AND CANCER

G.N. Schrauzer, University of California, San Diego Campus, Graduate School, Dept. of Chemistry, *P.O. Box 109, La Jolla, California* 92037 (D-IARC-79-718)

Determination of dietary intakes of trace elements in populations in different countries based on analyses of food consumption data is being undertaken. An international data bank is being developed. Correlations between apparent dietary trace element intake and cancer mortality are being computed to test aetiological hypotheses. The anticarcinogenic effect of selenium is being explored both experimentally and on the basis of epidemiological studies. The interrelationships between diet and cancer are being investigated on the basis of the protective effect of selenium and other trace elements against cancer. These computations are being undertaken for all major cancer sites and 28 different countries.

CORRELATION OF EPIDEMIOLOGICAL AND METABOLIC PARAMETERS IN RELATION TO LARGE BOWEL CANCER

B.S. Reddy, American Health Foundation Inc., Naylor Dana Institute for Disease Prevention, *Hammond House Rd., Valhalla, New York* 10595 (D-IARC-79-968)

The overall objective of this research program is to identify specific dietary components that either directly or indirectly cause large bowel cancer in man, and to elucidate the mechanisms related to, and the role played by dietary components and intestinal bacteria and their metabolites in the etiology of colon cancer. In order to achieve this objective, the cholesterol conversion pattern by fecal microflora from patients with colon cancer, adenomatous polyps, ulcerative colitis and familial polyposis and from healthy controls will be studied as well as the effect of mode of preparation and consumption of beef (cooked 'rare, medium or well-done') on the composition of fecal bile acids and cholesterol metabolites and on fecal bacterial beta-glucuronidase, 7alpha-dehydroxylase and cholesterol dehydrogenase activities in man.

INFLUENCE OF SMOKING ON CAUSES OF DEATH AMONG ASBESTOS INSULATION WORKERS

I.J. Selikoff, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Community Medicine, *5th Ave. at E. 100th St., New York, New York* 10029 (D-IARC-79-949)

On 1 January 1967 the entire membership, 17,800 men, of the Asbestos Workers' Union in the U.S.A. and Canada was registered. Smoking habits were recorded at the time of registration. The entire group has been followed prospectively from 1967 and death rates are being calculated taking smoking into account. For smoking-specific rates, the current data derived from the American Cancer Society's Cancer Prevention Study are being utilized, since this gives smoking-specific death rates 1960-1972. By the end of 1975, more than 2,000 deaths had occurred. Analysis is being undertaken according to cigarette, pipe and cigar smoking, age at beginning to smoke, amount smoked, duration of employment and duration from onset of employment, as well as other

parameters. Specific causes of death which are of interest include various types of cancer and asbestosis.

MORTALITY STUDY OF LEAD WORKERS

S.G. Selevan, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

Lead phosphate administered subcutaneously to rats has resulted in the induction of renal tumors and renal tumors have also been induced in rats by lead acetate-containing diets. Lead oxide appears to act synergistically with benzo(a)pyrene in pulmonary tumorigenesis in Syrian hamsters; lead is reportedly cumulative in the lung. Workers in lead smelters and battery plants breathe or ingest lead as a result of poor hygiene. Possible carcinogenic or co-carcinogenic effect deserves examination. Although the authors of a study on cancer among lead battery plant workers concluded that their results do not support a specific cancer risk, the data suggest that such a risk may be present. In order to further assess the possible excess cancer risk to lead exposure, a further retrospective cohort study is planned on workers exposed to lead and its compounds.

CASE-CONTROL STUDY OF THE RELATIONSHIP BETWEEN FEMALE HORMONE USE AND CANCER OF THE BREAST AND ENDOMETRIUM

D. Slone, Boston University, School of Medicine, Dept. of Medicine, *80 E. Concord St., Boston, Massachusetts* 02215 (D-IARC-79-873)

An epidemiological study of the case-control type will take place in the context of a large, ongoing study with the following objectives: (1) To design, test and implement an ongoing system of data collection as a resource for generating and testing hypotheses concerning effects of drugs used for long periods of time; (2) to monitor this data to identify previously unrecognized effects of such drugs; (3) to carry out ad hoc analyses of the data to evaluate hypotheses (both those arising from monitoring and from elsewhere); (4) to undertake ad hoc studies outside the monitoring system to provide for further evaluation of certain hypotheses; (5) to provide estimates of when drugs used for long periods appear to be safe. The hypotheses to be evaluated in this study are that female hormones are related to an increased risk of breast and endometrial cancer. The study will be based in hospitals throughout the U.S.A. Specially trained nurses will administer questionnaires to cases and controls to determine descriptive characteristics, prior female hormone and other drug exposure, and presence of known risk factors for cancer of the breast and endometrium. Between 400 and 500 women, each with breast cancer and endometrial cancer, and about ten times that number of controls will be interviewed.

ASBESTOS AND CANCER IN PATIENTS WITH LOW OR NO OCCUPATIONAL EXPOSURE

M. Warnock, University of California, San Francisco Campus, School of Medicine, Dept. of Pathology, *551 Parnassus Ave., San Francisco, California* 94122 (D-IARC-79-745)

Previous studies in this Department have failed to demonstrate a relation between numbers of asbestos bodies and the presence of carcinoma of the lung or gastrointestinal tract in workers with very low asbestos exposure. Asbestos bodies, however, represent only a part, and perhaps only a small part, of the total lung asbestos burden, which is composed of coated bodies as well as uncoated fibers. It is possible that a relation exists between numbers of uncoated asbestos fibers and the presence of bronchogenic carcinoma. This study will attempt to quantify and type the uncoated asbestos fibers as well as asbestos bodies at various sites in the lung. A new preparative method, already used for examining and identifying the nature of the cores of asbestos bodies by electron diffraction, will be used to identify further these same bodies by electron microprobe analysis. An additional preparative method has been devised for recovering uncoated asbestos fibers. Relations between numbers of coated and uncoated asbestos fibers, as well as their relative locations within the lung, will be tabulated, and an attempt will be made to correlate numbers or types of fibers with the presence or absence of carcinomas. It has previously been shown here that numbers of asbestos bodies are related to occupation; an attempt will be made to establish whether a similar situation exists for uncoated fibers or whether they are derived from the environment.

CANCER IN PERSONS EXPOSED TO EXOGENOUS ESTROGENS

F. Watman, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510 (D-IARC-79-760)

The purpose of this research is to estimate the range of cancer risk from prenatal exposure to exogenous estrogens among mothers and their exposed male and female offspring. Two matched control groups of unexposed mother-offspring pairs will be identified and the cancer incidence in these groups will be compared to that in the at-risk group. One group will be based on physician-matched controls, the second control group will be selected using Connecticut birth registration data. Cancer experience will be determined by linking the names of members of the cohorts to patients reported to the Connecticut Tumor Registry. All cancer sites will be considered, with particular attention given to reproductive system cancers. To date more than 800 exposed mother-offspring pairs and 800 physician-matched control pairs have been identified and detailed information has been abstracted from their prenatal medical records. Several thousand additional unexposed mother-offspring pairs have also been identified. These cases will be considered in a separate analysis in which the matched pairs are broken.

CANCER RISKS IN COSMETOLOGISTS

J.W. Meigs, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510 (D-IARC-79-759)

This study will investigate the incidence of cancer of all sites among cosmetologists who were licensed to practice in Connecticut before December 1965 and will provide a more definitive estimate of risk suggested by the preliminary results according to which cosmetologists may have increased risk of acute leukaemia. This extension will enlarge the study group from 12,000 to 17,000, including cosmetologists whose date of birth was previously unavailable. Follow-up status as of December 1978 will be determined for all cosmetologists. The expected number of cases of cancer by individual sites will be estimated by applying to the group at risk the cancer incidence rates of the general Connecticut population, specific for age, calendar year, sex and site. Cancer cases among the cosmetologists will be ascertained through December 1978 by computer linkage of the names in the study group with those reported to the Connecticut Tumor Registry.

SEROEPIDEMIOLOGICAL STUDY OF HERPES SIMPLEX VIRUS IN CARCINOGENESIS OF THE CERVIX

E. Stern, University of California, Los Angeles Campus, School of Public Health, Dept. of Public Health, *405 Hilgard Ave., Los Angeles, California* 90024 (D-IARC-79-735)

It is proposed to investigate by a longitudinal study a possible relationship between herpes simplex viruses (HSV), the development of cervical dysplasia, and its progression to cervical cancer. One of the critical issues is the timing of herpes infection in relation to onset of the neoplastic process and a feature of the proposed research is the serial observation and testing of patients to clarify the temporal relationship of herpes infection and carcinogenesis. In considering a longitudinal approach, the relatively low incidence of cervical cancer and the long latency present serious problems of sample size and duration of follow-up. The number of women in the study as well as duration of follow-up can be reduced by following a defined population of women who already have the cancer precursor, dysplasia of the cervix. We have been investigating the possible relationship of steroid contraceptives and carcinogenesis of the cervix by means of a long-term prospective study of women with dysplasia of the cervix. The proposed study on the role of HSV in carcinogenesis of the cervix uses this resource of clinical and laboratory data. Sera already collected from these patients will be used for serial viral antibody studies. Further follow-up of patients and collection of samples will continue.

CERVICAL CYTOLOGY PROGRAM

R.C. Steinkamp, State Dept. of Health, *4815 W. Markham St., Little Rock, Arkansas* 72205 (D-IARC-79-705)

Arkansas ranks 12th among the states of the U.S.A. with regard to mortality from uterine cervical cancer. The existence of rural communities, non-white populations and areas with low physician:population ratio constitutes high risk conditions. There is insufficient screening and follow-up. The program is designed to reach the high-risk woman by utilizing ancillary facilities in statewide local health departments, public health nurses and a system of newly developed colposcopy clinics. These clinics provide for definitive diagnosis for about 85-90% of women found to have abnormal Papanicolau smears. The program aims to follow up (1) all women with abnormalities to ascertain the course of dysplasias of the cervix and (2) all women with normal cytological smears prospectively in relation to epidemiological factors, socioeconomic status, oral contraceptives and other factors.

FAMILIAL AGGREGATION OF CANCER IN A MEXICAN-AMERICAN COMMUNITY

K.M. Weiss, University of Texas, Health Science Center at Houston, Graduate School of Biomedical Sciences, Dept. of Demographic & Population Genetics, *P.O. Box 20334, Houston, Texas* 77025 (D-IARC-79-1056)

A closed population of Roman Catholics of Mexican/Spanish ancestry for which birth, marriage, parenthood, and death records exist from its founding in

the mid-1700s to the present is being studied. These church, hospital, and civil records provide the data base for reconstructing families back to 1900 and before. Such families will be examined statistically to see if cancer mortality aggregates non-randomly among them, so as to determine heterogeneity in genetically based risk for various cancer sites. In addition, the fertility of victims of cancer will be ascertained to make short-term predictions of the proportion of cancer mortality which may be related to genetic factors. Environmental influences will be taken into account in the statistical methods used to assay the pedigrees. The age pattern of incidence for cancer, the effect of mortality from competing causes, and the changing incidence and age patterns of degenerative diseases in general, and cancer in particular, will be studied. This study will constitute both a complete cancer-epidemiological study of a rather uniform population and a cancer-genetic study.

THE EPIDEMIOLOGY OF GYNECOLOGICAL CANCER

N.S. Weiss, University of Washington, School of Public Health & Community Medicine, Dept. of Epidemiology, *4000 15th Ave. N.E., Seattle, Washington* 98105 (D-IARC-79-1071)

The objective of the study is to delineate the role of exogenous hormones in the aetiology of endometrial, ovarian, and vulvar cancer. All residents of selected counties in the states of Washington and Utah who develop one of these gynecological cancers during a two-year period are being identified through population-based cancer registries. Cases are interviewed and their responses compared to those of a random sample of women in the population. The interview is centered on use of exogenous hormones, recall being aided by displays of commonly used preparations.

ENVIRONMENTAL INFLUENCES ON CANCER MORBIDITY IN THE PITTSBURGH REGION

J.B. Andelman, University of Pittsburgh, Graduate School of Public Health, Dept. of Industrial Env Health Sciences, *4200 5th Ave., Pittsburgh, Pennsylvania* 15260 (D-IARC-79-1031)

This project involves the use of regression modelling techniques to determine if there are differences in cancer morbidity rates for water supplies (including sources and source types) which cannot be explained by available information concerning socio-economic status, housing density, industrialization, etc. Specifically, the Third National Cancer Survey cancer morbidity data for 19 different anatomical sites are being regressed against census tract data aggregated by water utility service areas. Residuals from these regressions are cross-classified separately with water service areas, water sources, and water source types to determine if the residuals are independent of these major water classifications.

GENETIC EPIDEMIOLOGY OF CANCERS AND OTHER MAJOR CHRONIC DISEASES

R.R. Williams, Utah Higher Education System, University of Utah, School of Medicine, Dept. of Internal Medicine, *1400 E. 2nd S., Salt Lake City, Utah* 84112 (D-IARC-79-1061)

Genetic predisposition and environmental influences are frequently suspected of acting either alone or, probably more often, together to result in the occurrence of cancer and other major chronic diseases (such as coronary artery disease). From geneological records of the Latter-Day Saints (LDS) Church (Mormons) in Salt Lake City a computerized pedigree file with 4-8 generations for a large proportion of Utah residents (75% LDS) is being constructed. Computer files of medical data including a 10-year computer file of incident tumour cases in the state of Utah and a 20-year file of death certificates are being linked to the pedigree file. Analyses will be performed to (a) estimate heritability of specific cancers (and other chronic diseases), (b) identify specific families with strong genetic predispositions, (c) elucidate specific genetic transmission mechanisms with environmental factors taken into account as penetrance functions. Major cancer sites include breast, lung, colon, prostate, and all other major sites.

SUPPORTED BY (No Supporting Organization Reported) funds n.a.

2.2205,

GENETIC EPIDEMIOLOGY AND NATURAL HISTORY OF BREAST CANCER

N.L. Petrakis, University of California, San Francisco Campus, School of Medicine, Dept. of Epidemiology & International Health, *551 Parnassus Ave., San Francisco, California* 94122 (D-IARC-79-743)

Epidemiological and experimental studies are underway to investigate host, agent and environmental factors associated with breast cancer. A working model has been developed that relates epidemiological evidence linking reproductive experience and the risk of breast cancer to our findings regarding breast secretory activity in different groups and evidence of secretion of exogenous substances through the breast. Current research focuses on genetic markers associated with breast cancer, cytopathologic characteristics of normal and malignant breast tissue, metabolic activation of mutagenic agents by breast tissue, and secretion of potentially carcinogenic substances in breast fluid. In addition, a study of women's beliefs and health practices concerning breast cancer is underway.

STATISTICAL ANALYSIS AND QUALITY CONTROL (SAQC) CENTER FOR A CENTRALIZED CANCER PATIENT DATA SYSTEM (CCPDS)

N.E. Breslow, Fred Hutchinson Cancer Research Center, Prog Epidemiol & Biostatistics, *1124 Columbia St., Seattle, Washington* 98104 (D-IARC-78-985)

The basic task to be performed by the SAQC/CCPDS project is to plan, develop, implement and operate a computerized system to deal with uniform acquisition, quality control, storage retrieval, and analysis of basic cancer patient data submitted quarterly by 19 comprehensive cancer centers located throughout the United States. Initial activity has been focused on: the establishment of a minimum cancer patient dataset to be used in common by all participating institutions; the development of training programs to assure a uniform interpretation of each item in the dataset from each institution and the assembling of computer hardware and software for editing and storing abstracts of approximately 50,000 diagnosed tumors each year. Quarterly summaries on the accumulated data, as well as special detailed reports on topics of interest to oncologists and cancer epidemiologists are provided to each participating institution. In the second project year, the SAQC staff will formulate plans to gather more detailed information on epidemiologic factors, tumor staging, and tumor histology.

CANCER INCIDENCE IN RELATION TO A SMELTER

L. Polissar, Fred Hutchinson Cancer Research Center, Epidemiology & Biostatistics Program, *1124 Columbia St., Seattle, Washington* 98104 (D-IARC-79-1069)

The population in parts of King, Pierce, and Kitsap Counties of Washington State, U.S.A., are exposed to air-borne and soil-deposited arsenic trioxide from a smelter in Tacoma. Arsenic exposure has been linked to respiratory cancer among the Tacoma smelter employees and has been implicated as a carcinogen in other industrial studies. The effect of arsenic on cancer risk in the exposed populations outside the smelter will be evaluated using data from a complete, areawide cancer registry.

PROSTATIC CALCIFICATION, PROSTATIC CARCINOMA AND BENIGN PROSTATIC HYPERTROPHY IN AMERICAN AND AFRICAN BLACKS

M.Y. Heshmat, Howard University, School of Medicine, Cancer Research Center, *2400 6th St. N.W., Washington, District of Columbia* 20001 (D-IARC-78-998)

The aims of this study are to (1) compare the frequency of prostatic calcification in blacks in Washington, D.C., Ibadan, Nigeria and Accra, Ghana, (2) study the association between prostatic calcification and carcinoma (latent and invasive) and benign prostatic hyperplasia in the three populations and (3) study the relationship between place of calcification (central or peripheral) and degree of calcification and prostatic carcinoma and hyperplasia in the same populations. In this continuing study, whole prostate glands are collected from consecutive necropsy cases. Whole glands with attached seminal vesicles were accessioned, entered into a blind study, weighed, step-sectioned at 4 mm intervals, processed, mounted on large slides, and stained with hematoxylin and eosin. All sectioned cases have also been examined by X-ray for calcification, 327 from the American material and 538 from the African study material.

A RECORD LINKAGE FEASIBILITY STUDY TO OBTAIN PREVALENCE AND INCIDENCE RATES FOR MULTIPLE MYELOMA IN US VETERANS

A.Z. Keller, U.S. Veterans Admin., Dept. of Medicine & Surgery, Regional Office, Research Service, *941 N. Capitol St. N.E., Washington, District of Columbia* 20421

Since all veterans with multiple myeloma, as for most diseases, are not seen in veterans hospitals, incidence and prevalence rates derived from data on hospitalized patients are underestimated. The present study investigates the feasibility of obtaining medical information on veterans from non-veterans hospital sources to merge with data from veterans hospitals. Information will be obtained from cancer registries, hospital records and death certificates in six geographical regions to permit computation of absolute rates of multiple myeloma by race, age, and geographical area. The denominators for these rates will be veterans living in these areas as reported by the United States Census Bureau. Environmental exposures will be studied in an effort to explain observed rate disparities by race, age and geography.

TOBACCO AND ALCOHOL USAGE, MARITAL STATUS, RELIGION AND OCCUPATION AS RISK FACTORS AMONG CIRRHOTICS AND NON-CIRRHOTICS WITH CANCER

A.Z. Keller, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Research Service, *50 Irving St. N.W., Washington, District of Columbia* 20422 (D-IARC-79-769)

This study is based on a 100 percent sample of 286 males with liver cirrhosis and cancer and a 2 percent sample of 374 males with cancer only who were discharged from the nationwide complex of United States veterans hospitals in a one year period. Cirrhotics and non-cirrhotics with cancer are compared in order to determine: 1) Whether the site distributions and relative risks of cancer are remarkably different by the amounts and types of alcohol consumed or tobacco smoked; 2) whether there are gradient shifts in the relative risks of cancer from one tissue or organ to another, when the uses of tobacco and alcohol range from the least to the greatest amounts; 3) whether the relative risks of cancer by anatomical sites are significantly different by marital status, religion and occupation; and 4) whether, histologically and anatomically, multiple primary cancers are in excess.

EPIDEMIOLOGICAL STUDY OF BENZENE EXPOSED WORKERS

N.K. Weaver, American Petroleum Inst., Dept. of Medicine & Biological Science, *2101 L St. N.W., Washington, District of Columbia* 20037 (D-IARC-79-773)

The objective of the study is to determine the mortality rates of workers exposed to benzene in petroleum operations. Workers having known exposures to benzene will be identified, and their mortality rates determined and compared with those of other groups. Secondary studies will include proportionate mortality from pooled company records; a study of effects on health, particularly blood counts, as they relate to benzene exposure; development of a job title dictionary for exposure dosage; and establishment of a prospective medical mortality and environmental study. If primary studies reveal excess mortality from specific diseases, especially leukaemia, latency periods, dose relationships and host factors will be studied.

MORTALITY-MORBIDITY STUDY AND TUMOR REGISTRY FOR PETROLEUM, REFINING, PETROCHEMICAL AND RESEARCH AND DEVELOPMENT WORKERS

N.K. Weaver, American Petroleum Inst., Dept. of Medicine & Biological Science, *2101 L St. N.W., Washington, District of Columbia* 20037 (D-IARC-79-774)

The objective of this study is to conduct a comprehensive prospective epidemiological investigation among petroleum industry workers as a means of determining possible health consequences of occupational exposure. A data gathering, reporting, and interpreting system appropriate for the conduct of a continuing epidemiological study will be established. Patterns of morbidity (illness), mortality and tumor occurrence will be identified and compared with the rates for a suitable control population. Relationships between morbidity and mortality patterns will be related to occupational characteristics, and trends in affected worker populations will be defined. The data received from participants will be analyzed and interim reports to each individual company on its own material made. The project will encompass all disease categories in the International Classification of Diseases and the morbidity portion of the study will be based on all sickness absences of five or more days' duration.

CERVICAL CYTOLOGY DEMONSTRATION PROJECT FOR SOUTHWESTERN AMERICAN INDIAN POPULATION

S.W. Jordan, University of New Mexico, School of Medicine, Dept. of Pathology, *University Hill N.E., Albuquerque, New Mexico* 87131 (D-IARC-79-911)

The objective of this study, in addition to providing cytological diagnostic services to a large group of American Indians and selected non-Indians, is to investigate certain epidemiological aspects of uterine cervical and endometrial cancer. Previous work has shown significant differences in histologically established age-specific rates of cervical carcinoma between Southwestern American Indians and Caucasians, and this work will be extended and amplified. Also to be examined will be the effect of cytological screening on mortality rates for cervical carcinoma. Non-Indian patients attending the University of New Mexico teaching hospital and clinics serve as the control group. Records of about 140,000 patients are currently available in cytology laboratory files in machine-retrievable format.

FAMILIAL AND GENETIC FACTORS IN MALIGNANCIES

J.J. Mulvihill, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Clinical Epidemiology Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205 (D-IARC-79-853)

OBJECTIVES: To document the occurrence of patterns of family aggregation of neoplasms. To study such families by genetic and laboratory investigations, in an effort to elucidate the degree to which heredity and/or the common familial environment contribute to the aetiology of neoplasms. To distribute tissue and blood specimens from such families to interested laboratory investigators, for aetiologic study by cytogenetic, immunological, viral and tissue culture methods. To identify genetic factors and disorders associated with cancer.

METHODS EMPLOYED: Interview of cancer patients with respect to family occurrence of cancer and other disorders, as well as information on prior medical and environmental history; documentation of history by obtaining appropriate vital records and hospital charts; collection and distribution of biological specimens from such families; review of hospital records of series of patients with selected genetic diseases or neoplasms; survey of childhood cancer death certificates in the U.S. since 1960 to identify sib aggregation.

COOPERATIVE EPIDEMIOLOGICAL AND PATHOLOGICAL STUDY OF COLON-RECTUM CANCER

O. Auerbach, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Senior Medical Investigators Laboratory, *Tremont Ave. & S. Centre St., East Orange, New Jersey* 07019 (D-IARC-79-903)

Preliminary epidemiological studies are underway to investigate the cause and origin of colon-rectum cancer. To date 2,886 colon-rectum specimens have been collected from the continental USA and Hawaii, Puerto Rico, and England. Efforts have been concentrated on 500 of these cases in which the colon-rectum was completely removed including the anal skin. The lesions were examined microscopically and the size, location and type of mucosal lesions recorded. A report of this investigation has been accepted for publication in Cancer. It is now planned to make a microscopic study of the remaining bowel in cancer cases from the London series in which every malignancy found arose in polyp, to see if there is any evidence of different patterns of neoplastic change.

STATISTICAL DATA MANAGEMENT AND COORDINATING CENTER FOR THE TYLER TEXAS ASBESTOS WORKERS PROGRAM

V.F. Guinee, University of Texas, University of Texas System Cancer Center, M.D. Anderson Hospital & Tumor Inst., Dept. of Epidemiology, *c/o Texas Medical Ctr., Houston, Texas* 77030 (D-IARC-79-1046)

The National Cancer Institute has established a complete medical surveillance program for a group of individuals who were exposed to amosite asbestos fibers in the course of their employment at a pipe insulation manufacturing plant in Tyler, Texas. The surveillance program is a collaborative effort, with the two primary components being the Tyler Asbestos Workers Program (TAWP) affiliated with the University of Texas Health Center at Tyler and the Statistical Data Management and Coordinating Center (SDMCC) directed through the Dept. of Epidemiology, the University of Texas System Cancer Center. The primary goal of TAWP is to make medical and scientific expertise and technology available to the affected workers and to study the pathogenesis and early detection of lung cancer induced by asbestos. The SDMCC is responsible for data collection and analysis of the total program, with particular interest in the epidemiological, laboratory and clinical data produced by TAWP/SDMCC activities.

VIRAL ETIOLOGY OF HUMAN MALIGNANCIES - IDENTIFICATION OF ANTIBODY TO HERPES SIMPLEX VIRUS (ABBREV)

J.L. Melnick, Baylor College of Medicine, School of Medicine, Dept. of Virology & Epidemiology, *1200 Moursund Ave., Houston, Texas* 77025 (D-IARC-79-1051)

Serum samples of patients with cervical cancer, breast cancer, and matched non-cancer control women are examined for antibody to individual HSV-2 induced polypeptides. The study attempts to answer the following questions: (1) Is there a generalized increase in the capacity to precipitate HSV early proteins other than VP 134 (a major early nonstructural polypeptide used in earlier reactivity tests) with the sera of cervical cancer patients? (2) What is the reactivity of sera from cervical cancer patients with HSV-2 'early' proteins? (3) What are the relative differences in the reactivity when 'late' proteins, instead of 'early' proteins, are used in the radioimmune precipitation test followed by polyacrylamide gel electrophoresis analysis of washed immune precipitates? Case-control differences will be studied in different geographic areas.

ANOVULATION AND THE EPIDEMIOLOGY OF BREAST CANCER

R.B. Wallace, University of Iowa, School of Medicine, Dept. of Preventive Medicine & Environmental Health, *Jessup Hall, Iowa City, Iowa* 52240 (D-IARC-79-815)

The objective of this study is to empirically investigate the relationship between menstrual cycle patterns and the subsequent onset of breast cancer. Also, using companion hysterologic studies, we have been measuring the hormonal characteristics of various menstrual cycle patterns in order to develop a pathophysiological hypothesis to explain some of the known breast cancer risk factors. The basic study is being performed in two phases. The first is a review of a cohort study of concurrently collected menstrual cycle patterns, in a group of women over a 45-year period. The women who exhibit breast cancers among this cohort have been identified and we are currently examining menstrual cycle patterns from the data base to see if those women who develop breast cancer can be discriminated from those who did not. Particular emphasis is placed on those menstrual cycle patterns that occur around the time of menarche, menopause, and birth events. Preliminary analysis has revealed that women with early menarche, late first parity, and late menopause, have characteristic menstrual cycle patterns that differ

from those women with the opposite characteristics. Study of this population has also allowed us to test the accuracy of recall of menstrual and reproductive events as the subject's complete records are available for analysis. We are also testing these hypotheses in case-control format, but results of this study are not yet available. This study is also testing various hypotheses relating to the consumption of thyroid hormone, oral contraceptives, oestrogens, and other medications and their relationship to subsequent onset of breast cancer. Among the initial findings is that there is no relationship between the prior consumption of thyroid hormone and the development of breast cancer, though such a relationship has been reported by others.

2.2220,
RELATIONSHIPS OF HUMAN AND BOVINE LEUKEMIA
K.J. Donham, University of Iowa, Inst. of Agricultural Medicine & Environmental Health, Dept. of Preventive Medicine & Environmental Health, *Oakdale Campus, Oakdale, Iowa* 52319 (D-IARC-79-816)
The epidemiological relationships of human leukemia and bovine lymphosarcoma in Iowa over the past three years have been studied. An excess of acute lymphocytic leukemia (ALL) in males, primarily in the most rural counties of Iowa, was found. There is also a statistically significant correlation of numbers of dairy cows and ALL in males. There is an even greater risk ratio in those counties where cases of bovine lymphosarcoma have been documented. Future research will deal with the refinement of the risks associated with human ALL and the rate of infectivity of the dairy cow population with Bovine Leukaemia Virus (BLV). A serological test will be performed on designated dairy cow populations and data from the Iowa Cancer Registry will be compared. An area that appears to have an excess of cancers will also be studied. This area also happens to be high in dairy cattle density. Various occupational and environmental factors will be studied to see if a relationship can be identified.

HEALTH STUDY OF PLUTONIUM WORKERS
J.H. Stebbings, University of California, Central Office, U.S. Dept. of Energy Los Alamos Scientific Lab., Health Division, *P.O. Box 1663, Los Alamos, New Mexico* 87545 (D-IARC-79-912)
Past and present plutonium workers from six major United States nuclear installations will be followed to determine age-specific mortality rates for all major causes of death, with special emphasis on cancer. Dose-response relationships will be estimated using systemic body burden data from urine tests. The study population, approximately 20,000 individuals, will include all workers with estimated body burdens above one nanocurie, random samples of exposed workers with lesser or no body burdens, and random samples of non-exposed workers from the same installations. The latter two groups of subjects will be group-matched by birth date, race, sex, and date of hiring. A cancer incidence study will be undertaken upon a subset of the study population; questionnaire studies of cardiovascular and chronic respiratory morbidity will also be carried out in that subgroup.

2.2222,
EPIDEMIOLOGY OF CANCER IN ADVENTISTS - A LOW RISK GROUP
R.L. Phillips, Loma Linda University, School of Health, Dept. of Biostatistics & Epidemiology, *Loma Linda, California* 92354 (D-IARC-79-719)
Seventh-Day Adventists (SDAs) are a conservative religious group who do not smoke or drink by church proscription. The age-sex adjusted mortality for most cancers unrelated to smoking among SDAs is 50-70 percent of the general population. The SDA church strongly discourages use of coffee, other caffeine beverages, highly refined foods and hot spices, recommending a low-fat, high-fiber lacto-ovo-vegetarian diet, as well as vigorous exercise. However, apart from smoking and drinking, there is great variation in the degree of adherence to these habits among SDAs, making them an ideal population to investigate the role of diet and other lifestyle characteristics in cancer. Further, the great variation in duration of exposure and age at first exposure to the SDA lifestyle provides an opportunity to determine the effect of lifestyle patterns early vs. late in life, as well as the effect of short-term vs. long-term patters of living. This on-going prospective study seeks (1) to confirm with incidence data the previously observed low cancer mortality among SDAs and (2) to determine the specific components of the SDA lifestyle which account for their apparent low risk of non-smoking related cancers. Collection of baseline data on demographic characteristics from 61,258 California SDAs, as well as detailed lifestyle characteristics from 46,000 of these subjects, is virtually complete. Continuation of this study for 5 more years will provide an average 8.5 years of follow-up for the 61,258 subjects with completed questionnaire data (525,412 person-years). Taking the expected low incidence into account an anticipated 2,481 new cancer cases (464 colon-rectal, 389 breast) will probably occur. All hospitalizations are reported during annual contact with each subject. After accounting for confounding factors, comparison of site specific cancer incidence between SDAs vs. the general population (as well as among subgroups of the SDA population with differing dietary and/or lifestyle characteristics) will be made.

FOLLOW-UP STUDY OF PATIENTS TREATED BY X-RAY EPILATION FOR TINEA CAPITIS
R.E. Albert, New York University, School of Medicine, Dept. of Environmental Medicine, *550 1st Ave., New York, New York* 10016 (D-IARC-79-930)
Children treated for tinea capitis between 1940 and 1959 at a major New York City dermatology clinic have been followed to examine the tumourigenic effects of X-radiation to the head (300 - 400 R). Some 2,215 irradiated patients and 1,395 patients given medications for tinea capitis have been traced. The groups are very well matched on sex, race, age and socioeconomic status. A third survey of these groups (average interval since tinea treatment - 20 years) is in progress and is showing a continued excess of basal cell carcinomas, and brain, thyroid and parotid tumors in the irradiated group.

CANCER IN MARRIED COUPLES
M.G. Curnen, Columbia University, School of Public Health, Dept. of Epidemiology, *600 W. 168th St., New York, New York* 10032 (D-IARC-79-933)
In this study, an attempt is made to determine whether the occurrence of prostatic cancer in married individuals is related to the occurrence of cancer in their spouses. Based on a review of medical records at Columbia-Presbyterian Medical Center in New York City from 1952 through 1973, this epidemiological study will determine whether the incidence of any type of cancer in spouses of prostatic cancer patients is significantly different from that in corresponding control groups of patients with benign hypertrophy of the prostate diagnosed during the same time period at the same institution. Any evidence of a greater than expected incidence of cancer in spouses of prostatic cancer patients would require confirmation in other medical centers and stimulate further research on possible mechanisms of transmission of cancer in marital partners.

CANCER IN PHYSICIANS - A COMPARISON WITH LAWYERS
M.G. Curnen, Columbia University, School of Public Health, Dept. of Epidemiology, *600 W. 168th St., New York, New York* 10032
This study is testing the hypothesis that physicians may be at an increased risk of dying with cancer because of their exposure to carcinogens in the milieu in which they work. Their mortality experience is being compared with that of lawyers who, in the USA, share the same lifestyle and socio-economic status. Professionals from both groups were either licensed to practice medicine or were admitted to the Bar in the State of Connecticut during the 1900-1975 period. A total of 11,527 male physicians and 6,318 male lawyers have been identified and followed until 1975. All sites of cancer are being investigated since the potential carcinogenicity of infectious agents, chemicals and radiation may affect different target organs. Age-specific mortality rates within five year age categories for physicians and lawyers grouped according to birth cohorts were computed by the modified life table method. The cancer mortality experience of physicians is further being analyzed according to specialities practiced during life.

EPIDEMIOLOGY OF CERVICAL CANCER - CHLAMYDIAE AND HERPES
J. Schachter, University of California, San Francisco Campus, George W. Hooper Foundation, *551 Parnassus Ave., San Francisco, California* 94122 (D-IARC-79-744)
The goal of this project is to determine whether any of the infectious agents under study are specifically associated with cervical cancer or dysplasia. Prevalence rates will be determined for infection with chlamydiae (debsoniae) - particularly trachoma-inclusion conjunctivitis (TRIC) agents and herpesvirus hominis (HVH) in the cervixes of women examined at the University of California, San Francisco. Those included in these studies will be normal women (routine examination and birth control advice), women being seen for genital tract inflammatory disorders (such as cervicitis and vaginitis), women being examined at the dysplasia clinic, and women who have once had cervical cancer. Isolation attempts will be made, with cervical scrapings taken at the same time as Papanicolaou smears. Serological studies will also be carried out in an effort to obtain evidence of any prior infection with herpes and TRIC agents. Rates for serological positivity for HVH-2 and TRIC agents will be directly compared for women with cervical cancer or dysplasia. Serological results will also be compared for patients with cervical cancer or dysplasia and those obtained in normal controls. These controls will be matched with patients by age, race, and several measures of sexual experience. In addition the various indices of sexual experience in patients with dysplasia or cervical cancer and in the controls will be compared.

METABOLIC EPIDEMIOLOGY OF COLON CANCER
B.S. Reddy, American Health Foundation Inc., Division of Nutrition, *Hammond House Rd., Valhalla, New York* 10595
The overall objective of this project is to develop key biochemical and/or microbial indicators which (1) distinguish high and low risk members of cancer families for development of colon cancer and (2) study the mechanism of cancer development in this high risk population. To achieve these objectives, feces from members of cancer families (50 colon cancer-prone symptomatic and 50 colon cancer-prone asymptomatic persons) and 50 age- and sex-matched healthy spouse controls will be analyzed for bile acids, cholesterol and its metabolites, B-glucuronidase, 7-dehydroxylase, cholesterol dehydrogenase and mutagens. The aim is to explore systematically the key metabolites by which a high-risk group for colon cancer is identified and characterized.

SEVENTH-DAY ADVENTISTS AND NON-SEVENTH-DAY ADVENTISTS CANCER SURVIVAL RATE STUDY

R.L. Phillips, Loma Linda University, School of Health, Dept. of Biostatistics & Epidemiology, *Loma Linda, California* 92354

OBJECTIVE: To compare Seventh-Day Adventist (SDA) and non-SDA cancer survival rates for breast and colon cancers; and to identify certain lifestyle characteristics which may account for differing survival rates between the two groups.

APPROACH: Identification of patients' religion will be made through hospital admission charts for those patients with breast and colon cancer reported to the California Tumor Registry from Loma Linda University Medical Center and White Memorial Hospital for the time period 1950-1976. This data will then be linked to the data collected by Lemon and Walden which will add lifestyle and family history information. Using life table analysis as well as comparisons of survival rates on specific lifestyle variables, such as dietary traits, studies will be performed to determine the effect of such variables on patient's survival.

CANCER IN ILLINOIS

S.S. Epstein, University of Illinois, Medical Center at Chicago, School of Public Health, Dept. of Occupational & Environmental Medicine, *Box 4348, Chicago, Illinois* 60680 (D-IARC-79-806)

The aim of this project is to investigate the contribution to cancer mortality of specific industrial manufacturing and processing activities in Illinois. Maps depicting mortality rates by county for Illinois on the basis of 1970-1976 data will be constructed. Major sources of carcinogens will be identified. Emissions data, ambient sampling, and dispersion models will be used to estimate levels of ambient exposures to carcinogens at different sites near the sources. Death certificates will be analyzed in order to compute mortality rates for cancer of several sites in tracts near the carcinogen sources. The tracts will be selected to control for confounding variables as much as possible. The relationship between cancer mortality rate, tract, and ambient exposure will be investigated. Possible carcinogen sources include: oil refineries, steel mills, metal refineries, chemical plants, and areas of high use of agricultural chemicals.

POSSIBLE ASSOCIATION OF DIETARY FACTORS AND NON-CONTRACEPTIVE EXOGENOUS OESTROGENS WITH BREAST CANCER

A.M. Nomura, Kuakini Medical Center, Dept. of Pathology, *347 N. Kuakini St., Honolulu, Hawaii* 96817 (D-IARC-79-795)

A case-control study of breast cancer is seeking possible associations of the disease with the use of exogenous oestrogens in post-menopausal women, and with histories of dietary intake high in animal protein and fat. The study design entails a comparison of breast cancer cases with neighborhood and hospital controls in three populations who differ greatly in their risks for breast cancer: Caucasians in Hawaii, Japanese Americans in Hawaii and indigenous Japanese in Fukuoka, Japan. Two hundred cases and their matched controls will have been analyzed for each of the three populations at the end of this projected five-year study.

MICROBIOLOGICAL FACTORS CONTRIBUTING TO COLON CANCER

H.F. Mower, University of Hawaii System, Manoa Campus, John A. Burns School of Medicine, Dept. of Biochemistry & Biophysics, *2444 Dole St., Pacific Biomedical Res. Ctr., Honolulu, Hawaii* 96822 (D-IARC-79-792)

Chemical causes of colorectal cancer are being sought by the use of bacterial mutagen assay to detect potential carcinogenic substances in human fecal samples. Preliminary epidemiological work has been done on the frequency of mutagens in feces of Japanese in Japan and Japanese in Hawaii, populations of low and high risk for large bowel cancer respectively. Five classes of fecal mutagens have been discovered, four of them present in higher amounts in the high risk Hawaiian Japanese than in the low risk Japanese Population. Two of these four mutagens are closely associated with the fecal transnitrosase. This is an enzyme which the investigators have discovered in certain strains of E. coli, various fecal bacteria and in human colon and stomach tissue. This enzyme can transfer nitroso groups from a wide variety of nitrosamines to a diverse group of amide acceptor molecules, such as simple primary and secondary amides, ureas and urethanes. The structure of the product is unknown but different from the structure of the N-nitroso-N-alkyl amides, ureas or urethanes. All products are direct acting mutagens on the Ames Salmonella Strain TA98. The enzyme is increased when beef is added to the diet of man or experimental animals. The identification and structure of these products will be studied. A newly discovered enzyme, mutagen suppressor enzyme, is also present in fecal bacteria. The enzyme will specifically destroy the product of the transnitrosase, converting these substances into N2, esters, or NO2 and the original acceptor molecule. Mutagen formation is thereby prevented. Both enzymes will be purified, characterized and studied. Mechanisms whereby diet and environmental effects alter the fecal mutagens, fecal transnitrosase and fecal mutagen suppressor enzyme will be sought.

MUTAGENS IN HIGH AND LOW RISK POPULATIONS FOR GASTRIC CANCER

M. Mandel, University of Hawaii System, Manoa Campus, School of Public Health, Dept. of Biochemistry & Biophysics, *Spalding Hall, Room 255, Honolulu, Hawaii* 96822 (D-IARC-79-791)

Direct acting mutagens as well as the transnitrosoase enzyme have been detected in biopsies of human gastric tissue. Gastric mutagens are usually similar to the fecal TA98 direct acting mutagens and increase on ingestion of beef in the same way. All tissue samples which contain mutagens also contain transnitrosoase but some tissue samples contain transnitrosoase without mutagens. Enzymes and mutagens are found most often in those regions of the stomach where gastric cancer is likely to be found. Human gastric tissues from low gastric cancer risk Causasians are being compared with tissues from high risk Japanese of Hawaii.

INVESTIGATION OF HISTOLOGICAL TYPES OF LUNG CANCER AMONG WOMEN IN THREE ETHNIC GROUPS IN HAWAII

M.W. Hinds, University of Hawaii System, Manoa Campus, Cancer Center of Hawaii, Epidemiology Program, *1997 East West Rd., Honolulu, Hawaii* 96822 (D-IARC-79-785)

This study will determine the histological type-specific incidence rates for lung cancer among Japanese, Chinese and Hawaiian/part-Hawaiian female residents of Hawaii and examine the association of cigarette smoking with lung cancer for each histological type and within each ethnic group. All available hospital records and pathology slides for the approximately 310 Japanese, Chinese and Hawaiian/part-Hawaiian women diagnosed with primary lung cancer during 1968-1977 will be reviewed. Pathology slides will be reviewed by two pathologists in a blind fashion, using standard histological criteria. Smoking history will be obtained from the medical records and estimates of the relative risk caused by smoking for each histological type of lung cancer will be made by comparison to a control group matched for sex, age, ethnic group and census tract of residence.

CASE-CONTROL STUDY OF CANCER OF THE BREAST, ENDOMETRIUM, AND OVARY, WITH EMPHASIS ON THE EFFECTS OF ORAL CONTRACEPTIVES

H. Ory, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, Evaluation Division, *1600 Clifton Rd. N.E., Atlanta, Georgia* 30333 (D-IARC-79-782)

This is a large cooperative case-control study, designed to: 1. Estimate the effect of oral contraceptive use on the risk of breast, endometrial, and ovarian cancer, especially among women with characteristics such as a) oral contraceptive use in the presence of benign breast disease and other breast cancer risk factors (family history of breast cancer, etc.); b) oral contraceptive use prior to first birth; c) use of sequential compared to combination oral contraceptives and d) prolonged total use of oral contraceptives. 2. Evaluate the pathological nature and prognosis of breast, endometrial, and ovarian cancer which occurs in association with oral contraceptive use when the association appears causal.

TETRACHLOROETHANE EXPOSURE AND SUBSEQUENT MORTALITY FROM CANCER IN U.S. ARMY VETERANS OF WORLD WAR II

J. Norman, National Academy of Sciences, National Research Council, Medical Follow-Up Agency, *2101 Constitution Ave. N.W., Washington, District of Columbia* 20418 (D-IARC-79-771)

Heavy exposures to chlorinated hydrocarbons in man result mostly from industrial chemicals and pesticides, but most exposures are recent and do not lend themselves to epidemiological investigation. One member of this class of compounds, tetrachloroethane, has had wide industrial use and was also used by the Army during World War II in the impregnation of clothing against mustard gas. Tetrachloroethane was used by men serving in Chemical Processing Companies, and it is this occupational exposure which is to be studied. The mortality experience of some 13,000 men (cases and controls) is to be studied to determine the effect of exposure to the chemical on cancer mortality.

CANCER AND STEROID HORMONES

H.W. Ory, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, Evaluation Division, *1600 Clifton Rd. N.E., Atlanta, Georgia* 30333 (D-IARC-79-781)

Hormones are suspected of being related to breast, ovary and endometrial cancer. However, the exact nature of this interrelationship has not been worked out completely. This prospective case-control study aims to assess the interaction of oral contraceptives and estrogenic hormones with risk factors of breast, ovary and endometrial cancer to determine if the factors operate independently, synergistically or not at all in producing the three cancers. The pilot phase of the project is currently under way. One hundred cases will be assessed to make sure that the methods intended for use work. Following this, a much larger study, to examine perhaps up to as many as 10,000 cases of the three diseases combined, is planned. The cases will be drawn from population-based tumor registries and the controls will be population-based also.

STUDY OF OVARIAN CANCER IN GREATER WASHINGTON

L. McGowan, George Washington University, School of Medicine & Health Sciences, Dept. of Obstetrics & Gynecology, *2121 Eye St. N.W., Washington, District of Columbia* 20037 (D-IARC-79-770)

In order to gain understanding of the apparently complex etiology of cancer of the human ovary, the National Cancer Institute (NCI) will design and over-

see an interview study of incident cases of ovarian cancer diagnosed in hospitals in the Washington, DC metropolitan area and controls discharged from the same hospitals. Although this form of malignancy is relatively common (17,000 cases per year in the U.S.) and is often fatal (10,000 deaths per year), very little is known of its causes. In the past decade, studies have clearly shown that the disease is associated with infertility and low fertility, but the mechanism remains to be elucidated. The existing suggestions of viral factors, of exogenous estrogenic factors, and of specific industrial exposures need further pursuit. NCI will conduct the study in collaboration with a local investigator experienced in the operation of an interview study of ovarian cancer, who will obtain the cooperation of the area hospitals and supervise the study staff. The study staff will be responsible for the identification of cases and controls, the interview of respondents, and the coding of data. NCI will design the protocol and the questionnaire, monitor the progress of the study, analyze the data, in cooperation with collaborating investigator.

FOLLOW-UP STUDY OF LIVER CIRRHOSIS

A.Z. Keller, U.S. Veterans Admin., Dept. of Medicine & Surgery, Regional Office, Research Service, *941 N. Capitol St. N.E., Washington, District of Columbia* 20421 (D-IARC-79-765)

More than 10,000 males with liver cirrhosis, divided into categories of age and race, will be followed up over a five to ten year period to determine their overall mortality experience, their site-specific rates of cancer incidence and their cancer risks by levels of tobacco smoked and alcohol consumed. Cirrhotic patients will also be comapred with a control group of the same age and race, but without liver cirrhosis, in order to evaluate differences in marital status, religious preference, residence and occupation. controls and cases will be selected from the 171 United States veterans hospitals located in 48 contiguous states, the District of Columbia and Puerto Rico. This study is a sequel to many previous studies on United States veterans which, generally, found increased risks of floor of mouth, uvula and soft palate, pharynx, esophagus and liver cancers among cirrhotics, heavy smokers, heavy drinkers or among patients with combinations of these attributes.

2.2242,

ALCOHOL, TOBACCO AND AGE FACTORS IN THE RELATIVE FREQUENCY OF CANCERS AMONG MALE NEGROES WITH AND WITHOUT LIVER CIRRHOSIS

A.Z. Keller, U.S. Veterans Admin., Dept. of Medicine & Surgery, Regional Office, Research Service, *941 N. Capitol St. N.E., Washington, District of Columbia* 20421 (D-IARC-79-766)

Because ethnic factors contribute to distinct distributions of many diseases in the United States and can frequently explain still other factors in their etiology, and because, further, a recent study yielded substantial data on white cancer patients with and without liver cirrhosis, there is a decided need for comparable data on Negroes. These data will facilitate valid racial comparisons in regard to tobacco and alcohol consumption, cancer sites and age disparities among males, with and without liver cirrhosis, and may delineate factors in cancer etiology which are specific to one race. Negro cases (with liver cirrhosis and cancer) and Negro controls (with cancer but not liver cirrhosis) from the 171 veterans' hospitals in the United States will be examined over a six year period. This research will endeavor to demonstrate the extent to which cirrhotics manifest significant excesses of specific digestive organ, oral cavity and pharyngeal cancers with regard to types and amounts of tobacco smoked and alcohol consumed. The probable roles of some occupational exposures in the pathogenesis of cancers in cirrhotics will also be assessed. Subsequent analyses will entail the comparison of data on Negroes with data, already published, on 286 white males with liver cirrhosis and cancer and on 374 white males with cancer only.

2.2243,

THE EPIDEMIOLOGY OF MULTIPLE MYELOMA IN UNITED STATES VETERANS

A.Z. Keller, U.S. Veterans Admin., Dept. of Medicine & Surgery, Regional Office, Research Service, *941 N. Capitol St. N.E., Washington, District of Columbia* 20421 (D-IARC-79-767)

The specific aims of this research are to determine overall rates of multiple myeloma incidence by race and age, and the specific incidence rates in each state and region of the United States by race among US males, diagnosed and treated in the 171 veterans hospitals located throughout the United States. This study will also determine if significant rate differences can be explained by either patterns of hospitalization or ratios of multiple myeloma patients to all other hospitalized patients by age, race and residence. The probable role of climatic factors in the incidence of multiple myeloma in each region will also be evaluated, in addition to occupational exposures, tobacco use and alcohol consumption. The multiple myeloma cases will comprise three year 100 percent sample of males discharged from United States veterans hospitals. Controls (matched to the cases on age, race and bed-sections in the hospitals) will be employed and the denominator for rates will derive from US Census Data on veterans. Finally, with multivariate techniques, the contributions of age, residence, birthplace, bed-sections in hospitals, tobacco use, alcohol consumption, occupations and, possibly, seasonality to any marked disparity in multiple myeloma incidence by race will also be made.

EPIDEMIOLOGICAL STUDY OF LEUKEMIA IN MESA COUNTY, COLORADO, U.S.A.

S.W. Ferguson, State Dept. of Health, Epidemiology Section, *4210 E. 11th Ave., Denver, Colorado* 80220 (D-IARC-79-746)

This is a descriptive and analytical study in Mesa County, Colorado, U.S.A., where the age-adjusted leukemia incidence rates are 2-2.5 times the expected, based on Colorado and U.S. data (41 observed: 20 expected in 1970-1976). In the 1950s and 1960s tailings from a uranium mill were used extensively in Mesa County for construction - as a backfill under basements and around foundation walls. For the analytical study the case-control approach is used. Leukemia patients, patients with other malignancies believed to be associated with ionizing radiation, and patients with cardiovascular disease are interviewed.

ESTIMATING THE INCREASES IN SKIN CANCER THAT WILL RESULT FROM INCREASING ULTRAVIOLET RADIATION

E.L. Scott, University of California, Berkeley Campus, School of Letters & Science, Dept. of Statistics, *Berkeley, California* 94720 (D-IARC-79-714)

Increasing ultraviolet radiation (from depletion of the stratospheric ozone or from other causes) will result in increasing skin cancer. The purpose of this study is to estimate the amount of the increase as a function of age, sex, locality, site, skin color, and other characteristics. Efforts are being made to ascertain the influence of microclimate, socioeconomic level, and other factors which may influence the observed increase in skin cancer. Separate studies are made for melanoma, non-melanoma, and keratosis in as much detail as possible; also for mortality, incidence, and prevalence.

EPIDEMIOLOGICAL STUDY OF THE INCIDENCE OF CANCER AS RELATED TO INDUSTRIAL EMISSIONS IN CONTRA COSTA COUNTY

D.F. Austin, State Dept. of Health Sciences, California Tumor Registry, *2151 Berkeley Way, Berkeley, California* 94704 (D-IARC-79-706)

The study aims (1) to test the hypothesis that the incidence of cancer of specific sites is higher in the population of the heavily industrialized section of Contra Costa County than in the population of the residential areas; (2) to determine whether any union or occupational groups in Contra Costa County have higher incidence rates for any cancer sites than other unions or occupational groups; (3) and to identify specific environmental factors associated with lung cancer incidence in Contra Costa County. Age, race, sex and site specific cancer incidence rates for an 8 year period will be calculated for the group of census tracts in the predominantly industrial section of Contra Costa County and for the remaining group of tracts in the residential section. Rosters of union members and other occupational groups will be matched with cancer incidence files of the Resource for Cancer Epidemiology. The number of cases observed will be compared in the San Francisco-Oakland SMSA. A case-control study of cancer patients in Contra Costa County will be performed. The site, sex and age of the cancer patients will be decided on the basis of the results of the cancer incidence data obtained in the first part of the study. A questionnaire designed to investigate variables, such as length of residence in Contra Costa County, socioeconomic status, smoking, occupation and other causative and contributing variables, will be administered to cases and controls.

HEALTH EFFECTS IN CHILDREN EXPOSED TO VINYL CHLORIDE

R.A. Zizkind, Science Applications Inc., Energy Environment Systems Division, *1801 Ave. of the Stars, Suite 1205, Los Angeles, California* 90067 (D-IARC-79-736)

Although a considerable body of occupational and laboratory toxicological data have demonstrated the carcinogenic action of vinyl chloride monomer (VCM), there appears to be little epidemiological information regarding health effects in children exposed to ambient levels of VCM. A pilot study consisting of a cohort of elementary school children who attended a school situated in close proximity to a PVC manufacturing plant will be conducted for potential health effects 10 to 20 years after exposure. Students will be grouped into three graduated exposure categories based upon estimates of total VCM concentrations received. Plant production history will be linked with pupil records, air monitoring data and dispersion calculations to subgroup the cohort. A number of mortality and morbidity indicators and data bases will be examined in order to contrast all exposure groups with zero exposure population.

RETROSPECTIVE COHORT MORTALITY STUDY OF DRY CLEANING WORKERS EXPOSED TO PERCHLOROETHYLENE

S.D. Kaplan, S R I International, Center for Occupational & Environmental Safety & Health, *333 Ravenswood Ave., Menlo Park, California* 94025 (D-IARC-79-738)

Perchloroethylene is a principal solvent in the dry cleaning industry. This chlorinated hydrocarbon has been shown to cause liver cancer in one strain of mice but not in one strain of rats. The objectives of the study are to identify a population of at least 2,000 individuals in dry cleaning facilities exposed to perchloroethylene as primary solvent and not previously exposed occupationally to either trichloroethylene or carbon tetrachloride who were employed for at least 12 months before 1960, obtain sufficient data to make possible calculation of expected mortality as a function of exposure, carry out follow-up, obtain death certificates and analyze and interpret the results. Eligibles for the cohort have been identi-

fied from four union locals, supplemented by solvent histories from sources including: equipment manufacturers and distributors, solvent distributors, and industry representatives. Follow-up will be through the Social Security Administration supplemented as needed by Motor Vehicle Registration and the Tel-Credit Bureaus. A modified life table analysis will be performed.

RETROSPECTIVE COHORT MORTALITY STUDY OF PRIESTS

S.D. Kaplan, S R I International, Center for Occupational & Environmental Safety & Health, *333 Ravenswood Ave., Menlo Park, California* 94025

Several case-control studies have suggested that men who are more sexually active are at higher risk of cancer of the prostate. Roman Catholic priests should represent a low risk group and offer the best test of the hypothesis. The purpose of this study is to examine the mortality experience of Roman Catholic priests, particularly for prostatic cancer. The standardized mortality ratio (SMR) for prostatic cancer and other causes of death will be calculated. The anticipated finding of a low SMR for prostatic cancer will be the best indication that sexual intercourse is a risk factor for this disease. Data have been collected from 31 Dioceses on active and retired diccesan priests during the year 1949. Information collected included name, date of birth, date of ordination and, for those deceased, date and place of death. The anticipated cohort size is 8,000 to 10,000 dependent upon additional diocesan cooperation. Death certificates will be obtained for deceased cohort members and cause of death will be coded by a trained nosologist. The anlysis will be by a modified life table program.

EPIDEMIOLOGY OF PANCREATIC CARCINOMA AND IDENTIFICATION OF HIGH-RISK GROUPS

T.M. Mack, University of Southern California, School of Medicine, Dept. of Pathology, *2025 Zonal Ave., Los Angeles, California* 90033 (D-IARC-79-727)

The objectives of this research are to study the epidemiology of cancer of the pancreas, to formulate causal hypotheses and to identify groups at high risk of developing this tumor. A large case - control study, to be performed in Los Angeles County, has been designed to permit simultaneous examination of multiple antecedent risk factors. Cases with cancer of the pancreas will be identified by the Los Angeles County University of Southern California Cancer Surveillance Program. questionnaire has been designed to obtain data on occupational and on environmental exposures - tobacco and alcohol consumption, diet, and medical history and treatment. It will be administered to both cases and neighborhood controls as soon as possible after the cases have been diagnosed. Standard matched-pair analyses of multiple variables will be performed on the data from the questionnaire.

MALIGNANT MELANOMA - A CASE-CONTROL STUDY IN LOS ANGELES

T.M. Mack, University of Southern California, School of Medicine, Dept. of Pathology, *2025 Zonal Ave., Los Angeles, California* 90033 (D-IARC-79-729)

The annual incidence of malignant melanoma in Los Angeles is about 10 per 100,000 and appears to be increasing. A case-control study has been designed to test and formulate causal hypotheses and to identify groups at high risk. The specific aims of this study are: 1) To quantify the risk of persons for melanoma in relation to job, medical history and particular patterns of behavior, inheritance and skin characteristics, 2) To distinguish between the determinants of risk to different body sites and the determinants of different pathological types. Cases with malignant melanoma will be identified by the Los Angeles County University of Southern California Cancer Surveillance Program. A questionnaire designed to obtain data on occupational and environmental exposures, behavioral patterns in the sun, medical history and treatment, and skin features will be administered to both cases and controls. In addition, skin color will be determined for cases and controls.

EPIDEMIOLOGY OF BENIGN BREAST DISEASE

G.H. Spivey, University of California, Los Angeles Campus, School of Public Health, Dept. of Public Health, *405 Hilgard Ave., Los Angeles, California* 90024 (D-IARC-79-734)

The aim of the study is to examine the epidemiology of major types of benign breast disease and to compare identifiable risk factors for benign diseases with known risk factors for breast cancer. At the same time a histological classification scheme based on grading of cellular atypia in comparison with the conventional histological classification will be examined. Approximately 1,000 women with first biopsies for benign breast disease in participating hospitals will be admitted to the study by a sampling mechanism designed to represent the spectrum of histological types. Histology slides will be reviewed by two independent pathologists and classified on two separate schemes. A group of about 200 women with breast cancer will also be included. Two types of controls will be used, a hospital control and a friend control. Information on epidemiological characteristics will be obtained by questionnaire. The questionnaire seeks responses on a wide range of topics including environmental influences, familial cancer patterns, medical, maturation, and reproductive history, and various other endocrine-related subjects. Epidemiological characteristics of different histological types of benign breast disease will be compared to each other and to those of breast cancer.

EPIDEMIOLOGY OF INTRACRANIAL NEOPLASMS

S. Preston Martin, University of Southern California, School of Medicine, Dept. of Pathology, *2025 Zonal Ave., Los Angeles, California* 90033 (D-IARC-79-732)

A large case-control study of two subgroups of patients with primary intracranial neoplasms is to be performed in Los Angeles County: intracranial tumors of all histological types first occurring in children and young people under age 25 from 1972-1977; and incident intracranial meningiomas in men from 1972-1975. The study has been designed to test the hypothesis that previous radiation exposure is causally related to the development of these tumors, to test previously suggested causal associations, to discover new associations and to delineate the characteristics of the high risk groups. Cases with specified intracranial tumours will be identified by the Los Angeles County-University of southern California Cancer Surveillance Program. Questionnaires have been designed to obtain data on radiation exposure, occupation, consumption of tobacco and drugs, medical history, and family history of tumors. Standard matched pair analyses of multiple variables will be performed.

CASE-CONTROL STUDY OF IMMUNOBLASTIC LYMPHADENOPATHY AND HISTIOCYTIC LYMPHOMA

B.E. Henderson, University of Southern California, School of Medicine, Dept. of Pathology, *2025 Zonal Ave., Los Angeles, California* 90033 (D-IARC-79-726)

In 1964, Lukes and Collins suggested a new classification of non-Hodgkin's lymphomas based on morphology and function of the cell type involved, thus providing a meaningful basis for epidemiological study of lymphomas. Recently a distinctive pathological lesion denoted lymphoid tissue immunoblastic lymphadenopathy (IBL) or angioblastic lymphadenopathy (ABL) has been identified. Although not a malignant process, the clinical course is often rapidly progressive with death resulting from infection. In some patients a true malignancy ensues, an immunoblastic sarcoma or histiocytic lymphoma by the Rappaport Classification. Follow-up of patients with IBL and/or histocytic lymphomas questioning them about initial onset of symptoms, antecedent environmental exposures relative to occupation, medication, and residence may elucidate aetiological agents involved, and a family history may provide answers to questions about a genetic predisposition. Laboratory studies include cell surface markers on a portion of the patients, HL-A and B cell typing, immunoglobulin measures, and various viral antibody titers. Controls are matched for age, race, sex and socioeconomic status.

2.2257,

A MORBIDITY AND MORTALITY FOLLOW-UP STUDY OF WOMEN TREATED FOR HYPERTHYROIDISM

D.A. Hoffman, U.S. Dept. of Health & Human Services, Public Health Service, Food & Drug Admin., Bureau of Radiological Health, Epidemiology Studies Branch, *5600 Fishers Ln., Rockville, Maryland* 20857

Radioiodine (131I) is now the treatment of choice for persons over the age of 20 years. Although there have been several studies of the possible delayed effects of radioiodine, they have been either too small or have not followed these patients for a long enough time to evaluate adequately the possible carcinogenic effects. The objective of this study is to follow up female patients treated for hyperthyroidism at the Mayo Clinic between 1946 and 1964. This is part of the population that was originally followed in the National Cooperative Thyrotoxicosis Follow-Up Study. Risks of morbidity and mortality, particularly from malignant neoplasms, will be evaluated. The study will attempt to determine if patients treated with therapeutic doses of 131I are at an increased risk of developing malignant neoplasia compared to patients treated for the same condition with non-radiation modalities. The study design is that of a non-concurrent prospective approach. Eligibility criteria for inclusion in the study cohorts include: 1) treated at the Mayo Clinic for hyperthyroidism between January 1, 1946 and December 31, 1964; 2) a confirmed diagnosis of hyperthyroidism; and 3) United States residency. After review of the Mayo Clinic records, a total of 3,696 white females were ruled eligible for inclusion in the study cohorts. The distribution of patients in the various treatment groups is: 1,004 treated with 131I, 2,141 surgically treated, 426 received both 131I and surgical treatment, and 125 received antithyroid drugs. The medical records of these patients have been abstracted for medical and demographic information. Because the patients were not randomly assigned to the treatment groups, the bases for selection for a particular therapy will be evaluated in order to minimize potential selected biases. Dosimetric information for those patients treated with 131I is being collected in order to estimate various organ doses. Follow-up of these patients is being conducted via mail.

2.2258,

NATIONAL CANCER INSTITUTE PROGRAM OF CANCER SURVEILLANCE, EPIDEMIOLOGY AND END RESULTS (SEER PROGRAM)

J.L. Young, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Biometry Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205 (D-IARC-79-855)

The SEER Program was developed in response to the Natonal Cancer Program requirements for assessing as currently as possible the magnitude of

the cancer problem in the United States and for identifying factors related to cancer risk and/or patient survival. The 'cancer problem' has been interpreted to include: 1) newly diagnosed cancer cases that might have been prevented by altering host or environmental conditions and 2) deaths due to cancer that might have been prevented by earlier cancer diagnosis coupled with optimal therapeutic approaches. Therefore, the SEER Program has among its objectives: 1) To assemble and report on a periodic basis, estimates of cancer incidence in the United States. 2) To monitor annual cancer incidence to identify unusual changes in specific forms of cancer occurring in groups defined by parameters of geographical, demographic and social characteristics of the population. 3) To provide continuing information on changes over time in extent of disease at diagnosis, trends in therapy and associated changes in cancer patient survival and 4) To promote the development of hypotheses and specific studies designed to identify cancer aetiological factors (environmental/occupational, sociocultural, etc.) and factors related to patient survival.

2.2259,

EPIDEMIOLOGY OF CANCER AMONG MORMONS

J.E. Enstrom, University of California, Los Angeles Campus, School of Public Health, *405 Hilgard Ave., Los Angeles, California* 90024 (D-IARC-79-722)

The standardized mortality ratio (SMR) for total cancer in 350,000 California Mormons during 1968-1975 and 750,000 Utah Mormons during 1970 -1975 compared with US whites is about 50 percent for 'active' males, about 65 percent for all males, and about 75 percent for all females. For active males the SMR is about 25 percent for smoking-related cancer sites and about 65 percent for all other sites. Mormons are a health-conscious religious group, who appear to be similar to US whites in many respects, such as diet, socio-economic status, and urbanization, but who use substantially less tobacco, alcohol, coffee, and tea than the general population. 'Active' Mormons, and leaders known as High Priests and Seventies, abstain almost entirely from tobacco, alcohol, and caffeine. However, the reasons for the low Mormon cancer rates are largely unknown, primarily because there are no detailed data available on their health characteristics. The objective of this study is to pursue the descriptive mortality data with a questionnaire survey and prospective mortality follow-up of 'active' California Mormon adults, specifically High Priests and their wives. The survey will obtain detailed demographic, life style, dietary, occupational, and medical history data on a representative sample of about 1,000 individuals and limited demographic and life style information on about 20,000 additional persons. Mortality follow-up will be conducted on this cohort for four years. Additional church-based mortality data will be collected for all California Mormons during the years 1960-1967 and 1976-1979 and for all Utah Mormons during 1976-1979, to increase the statistical reliability of the existing data summarized above. The data on life style and health-related characteristics of 'active' California Mormons will be compared with their detailed cancer mortality rates. Distinctive differences between these Mormons and other comparison groups will be highlighted.

SUPPORTED BY (No Supporting Organization Reported) funds n.a.

2.2260,

EPIDEMIOLOGY OF GASTRIC CANCER IN CHILEAN COHORTS

R. Armijo, University of California, Los Angeles Campus, School of Public Health, Dept. of Epidemiology, *405 Hilgard Ave., Los Angeles, California* 90024 (D-IARC-79-721)

It is proposed to pursue collaborative epidemiologic studies in Chile: (1) To determine the incidence and mortality from stomach cancer in cohorts defined endoscopically to have lesions which might be precursors of malignancy: intestinal metaplasia, chronic atrophic gastritis and gastric ulcer; (2) to observe histological changes in the gastric mucosa of patients with these conditions which may be indicative of the natural history of stomach cancer; (3) to develop a model of the natural history of stomach cancer; and (4) to look for environmental factors, including exposure to nitrates, which occur more frequently among persons who develop stomach cancer. Two cohorts of individuals with an endoscopic diagnosis of chronic atrophic gastritis, gastric ulcer or normal panendoscopy will be followed up for the occurrence of stomach cancer: a historical cohort of approximately 22,500 persons diagnosed at nine collaborating hospitals in high, low and intermediate risk areas between 1975 and June 1979 and a concurrent cohort of approximately 20,400 persons diagnosed between July 1979 and June 1983. A third cohort of 800 persons undergoing a histological diagnosis of intestinal metapiasia, chronic atrophic gastritis or gastric ulcer between July 1979 and June 1983 will be followed annually for histological changes. Follow-up will continue through June 1983 providing 171,192 person years of follow-up of the historical and concurrent cohorts and 1,561 person years of follow-up on the special cohort. These studies should identify persons who are at high risk of developing stomach cancer and should suggest histological and environmental factors important in the natural history of stomach cancer, thus facilitating implementation of intervention techniques with a resulting decline in the incidence and case fatality of stomach cancer.

REVIEW OF BILE DUCT CARCINOMAS

R.L. Peters, University of Southern California, School of Medicine, Dept. of Pathology, *2025 Zonal Ave., Los Angeles, California* 90033 (D-IARC-79-716)

As a follow-up on an earlier study of changing patterns of hepatocellular carcinoma, a similar study embracing autopsy material from the Los Angeles County Hospital 1945 to 1978 dealing with bile duct carcinomas has been undertaken in an attempt to establish the presence or absence of changing patterns of that tumor.

REVIEW OF INCIDENCE AND CHANGING PATTERNS OF LIVER TUMORS IN LOS ANGELES

R.L. Peters, University of Southern California, School of Medicine, Dept. of Pathology, *2025 Zonal Ave., Los Angeles, California* 90033 (D-IARC-79-717)

As part of an epidemiological study of tumors in Los Angeles County, a broad survey of tumors of the liver is being undertaken. All liver tumors diagnosed at biopsy or autopsy in the County of Los Angeles are microscopically reviewed, terminology and diagnoses are standardized and patient information regarding age, sex, race and past have dealt with death certificate diagnoses only or have accepted submitted diagnoses; this is an attempt to diagnose more precisely the types of tumors to see whether a low incidence tumor, previously buried in the overall designation of 'liver cancer', is showing a change in incidence.

FOLLOW-UP OF FLUOROSCOPICALLY EXAMINED TUBERCULOSIS PATIENTS IN RELATION TO CANCER INCIDENCE

R.R. Monson, Harvard University, Boston Campus, School of Public Health, Dept. of Epidemiology, *55 Shattuck St., Boston, Massachusetts* 02115 (D-IARC-79-868)

There is current interest in instituting mass screening programs of mammography to detect breast cancer in early stages. However, there is concern that the radiation used may itself have harmful side effects. In this study, the association between radiation received as a result of fluoroscopic examination during air-collapse therapy for tuberculosis and cancer is being assessed. The occurrence of other diseases both in relation to radiation and to isoniazid therapy will also be examined. This is a retrospective cohort study of approximately 9,000 women and men who were treated for tuberculosis in Massachusetts from 1930 onwards. These persons will be followed up from records and other sources. Rates of mortality and cancer morbidity will be compared internally, between radiated and non-radiated patients or between patients treated with and without isoniazid, and externally, with population mortality and cancer morbidity rates.

MORTALITY AMONG WORKERS IN THE METAL POLISHING, BUFFING, AND PLATING INDUSTRY

A.E. Blair, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., *9000 Rockville Pike, Bethesda, Maryland* 20205 (D-IARC-79-843)

Workers in the metal polishing, buffing, and plating industry are exposed to a number of potentially hazardous substances (metal dusts, cyanide solutions, solvents and degreasers). To evaluate the mortality experience of this group and to provide clues concerning the carcinogenicity of certain occupational exposures, the distribution of causes of death among 3,000 past members of the Metal Polishers, Buffers, Platers, and Helpers International Union will be compared with the distribution in the general population.

BLADDER CANCER, LEUKEMIA AND LYMPHOMA AMONG NEW YORK AND WISCONSIN DAIRY FARMERS - A DEATH CERTIFICATE STUDY

A.E. Blair, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., *9000 Rockville Pike, Bethesda, Maryland* 20205 (D-IARC-79-842)

A few studies have suggested that dairy farmers have elevated mortality from bladder cancer, leukemia, and lymphoma. To evaluate this lead, 300 deaths from each neoplasm in heavy dairying counties in New York and Wisconsin were individually matched to one control (dying of some other disease) of the same age, race, sex, year of death and county of residence. Type of farming operation for case and control farmers will be determined using records from the State Cooperative Extension Service. The proportions of death certificates listing farmer as the usual occupation and the type of farming operation will be compared in the cases and controls.

CAUSES OF DEATH AMONG TOBACCO WORKERS

A.E. Blair, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., *9000 Rockville Pike, Bethesda, Maryland* 20205 (D-IARC-79-841)

The objective of the study is to determine whether workers employed in tobacco processing plants experience unusual cancer mortality patterns that may suggest exposure to carcinogenic agents. The study group consists of approximately 3,000 deaths among members of the Tobacco Workers Union reported in the union journal since 1957. The tobacco workers will be compared with the experience of the general population.

IMMUNOLOGICAL AND MOLECULAR HYBRIDIZATION STUDIES OF NASOPHARYNGEAL CARCINOMA

D.V. Ablashi, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Laboratory of Cellular & Molecular Biology, *9000 Rockville Pike, Bethesda, Maryland* 20205

Epstein-Barr Virus (EBV) is considered a major factor in nasopharyngeal carcinoma (NPC). The study aims to further assess the role of EBV in terms of etiology, diagnosis/prognosis and other environmental and genetic factors essential in defining the populations and individuals at risk. Studies include EBV-serology (humoral and cell-mediated), virology (attempts to isolate EBV and to compare it with known EBV isolates) and attempts to propagate epithelial cells from biopsies, examination of the HLA profile of cases, detection and examination of EBV genome expression in biopsy material by nucleic acid hybridization, review of the histopathology of all such cases and an attempt to prepare somatic cell hybrids to detect EBV receptors. Malaysia has a high incidence of NPC and has subpopulations consisting of Malayans, Indians and Chineses, whereas West Germany and the USA are low NPC incidence areas. However, in USA, NPC cases include Chinese, white

and black populations and Alaska Eskimos. In Algeria NPC ranks as the number four cancer in males. There are also two age peaks in this population. Since young age NPC has been observed in the black population in some southern states of the USA, Algerian NPC would provide an excellent comparison. Histopathological slides from West German American NPC cases have been circulated for review to resolve differences in interpretation. Examination of approximately 14 cases of German NPC with more than 30 cases from Algeria suggests that antibodies to EBV antigens are much higher in Algerian cases. Data also show that antibodies to EBV are higher in American than in West German NPC. Attempts to propagate epithelial cells from NPC biopsies in vitro were unsuccessful.

EPIDEMIOLOGY OF ACUTE CHILDHOOD LEUKEMIA

M. Szklo, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Epidemiology, *615 N. Wolfe St., Baltimore, Maryland* 21205 (D-IARC-79-835)

Malignant diseases are the second leading cause of death in U.S. children, with leukemia accounting for about 50% of all childhood cancer deaths. Although a number of factors have been implicated in the etiology of childhood leukemia, including ionizing radiation and chemical agents, the etiology of most childhood leukemias remains unexplained. This case-control study aims to assess environmental influences in childhood leukemia, including factors which may act in utero or in early life. The study population consists of children identified in three metropolitan areas in the U.S. (Baltimore, Philadelphia and Washington, D.C.). Three groups of about 50 children were individually matched by age, sex, race and hospital of diagnosis: children with acute leukemia, children with other malignancies, and children without malignancies. Interviews have been conducted among parents of these children, and data are now being analyzed.

ENVIRONMENTAL EPIDEMIOLOGY OF PANCREATIC CANCER

L. Gordis, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Epidemiology, *615 N. Wolfe St., Baltimore, Maryland* 21205 (D-IARC-79-828)

Cancer of the pancreas is the fourth leading cause of death due to cancer in the United States, exceeded by cancer of the lung, colon and rectum, and prostate. This case-control study is designed to investigate environmental factors that may be associated with pancreatic cancer. Cases with pancreatic cancer and two groups of controls -neighborhood controls and hospitalized patients without cancer - and their families will be interviewed. Patients with a diagnosis of pancreatic cancer will be ascertained concurrently from the onset of the study for a period of three years. Cases will be identified from: review of hospital records, pathology records, survey of surgeons and internists, and review of death certificates. Wherever possible, the original slides of biopsy or surgical excision as well as pathology and/or autopsy reports will be obtained and reviewed for verification of diagnosis by a consultant pathologist who will not have the clinical data available to him prior to review of the slides. Patients will be interviewed as soon as is practical after diagnosis, generally during their post-operative convalescence. The spouse or closest relative will also be interviewed. A similar approach will be used for ascertaining information about controls. Data to be obtained in the interviews include: (1) demographic characteristics; (2) past medical history; (3) use of alcohol or tobacco; (4) detailed life-time occupational history; (5) chemical and radiation exposures; and (6) family history of pancreatitis, other digestive diseases, diabetes, or cancer.

LUNG CANCER IN LOUISIANA

H. Rothschild, Louisiana State University, Medical Center, School of Medicine, Dept. of Medicine, *1542 Tulane Ave., New Orleans, Louisiana* 70112 (D-IARC-79-824)

The aim of the proposed project is to investigate genetic and environmental factors that may account for the high mortality due to cancer of the lung in southern Louisiana. Approximately 800 deaths due to cancer of the lung were reported during the seven year (1971-1977) period in ten target parishes (counties). Histopathology has been collected and is being evaluated on almost all deceased persons. Surviving relatives of each person designated as having died of lung cancer are being interveved concerning the occupation and familial relationships of the deceased. The data on the subjects will be compared with data on controls matched for age, sex, race, and place of residence. Because previous studies have shown a possible relationship between ancestry and cancer, the coefficient of inbreeding will be quantitated, and that coefficient correlated with the incidence of lung cancer. Possible familial relationships will be computer-analyzed by the Russell Soundex System.

AMERICAN CANCER SOCIETY'S PROSPECTIVE EPIDEMIOLOGICAL STUDY

E.C. Hammond, American Cancer Society Inc., Dept. of Epidemiology & Statistics, *777 3rd Ave., New York, New York* 10017 (D-IARC-79-935)

Large scale prospective studies can provide data that are excellent sources for leads to cancer causation in humans. Analyses of mortality from cancer and other diseases from these studies can demonstrate the association of various aetiologic factors with mortality from different causes. Detailed questionnaires were collected from more than one million men and women by volunteers of the American Cancer Society who successfully traced nearly 99 percent of the subjects. Copies of death certificates for the deaths were obtained from state health departments. Follow-up was discontinued in 1972, but a small subgroup (about 1-5 percent of the survivors in 1972) are still being traced in 1978. These are 'long-lived' subjects (born before 1888 if a male, before 1886 if female). The purpose of this study is to determine what factor or factors are associated with not getting cancer.

RISK OF BREAST CANCER IN WOMEN WITH BENIGN BREAST LESIONS USING THE ORAL CONTRACEPTIVE

S. Graham, State University of New York, Buffalo Campus, School of Arts & Letters, Dept. of Sociology/Social & Preventive Medicine, *3435 Main St., Buffalo, New York* 14214 (D-IARC-79-925)

At least one investigator has found a higher risk of breast cancer in those women using the oral contraceptive who have a history of benign lesions than in women without such lesions. Arrangements have been made with Dr. Takuma Nemoto to administer a simple two-page questionnaire to women with breast cancer at the Roswell Park Memorial Institute. Age-matched controls from the dermatology service at the Roswell Park Memorial Institute will be used. It is anticipated that approximately 300 breast cancer patients can be surveyed per year at the Institute. The questionnaire administered contains questions dealing with the major hypotheses of breast cancer aetiology, including parity, age at first pregnancy, lactation, and the like, as well as questions dealing with use of the various oral contraceptives and a history of past benign breast lesions. Information on the physician prescribing and the hospital and physician treating the patient is obtained so that statements made can be corroborated through medical records. To date, 125 case and 48 control questionnaires have been completed.

HISTOLOGICAL FINDINGS IN BRONCHIAL EPITHELIUM IN RECENT AUTOPSIES

O. Auerbach, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Senior Medical Investigators Laboratory, *Tremont Ave. & S. Centre St., East Orange, New Jersey* 07019 (D-IARC-79-905)

During the past two decades tar and nicotine content of American cigarettes have been greatly reduced. Although lung cancer death rates have continued to rise, evidence from recent epidemiological studies shows that mortality rates have now started to decrease. If reduction of tar and nicotine reduces the risk of lung cancer, then the degree of histological changes in the tracheobronchial tree of men who were autopsied in recent years would be less than in men who died 15 or more years ago. If this could be shown, it would lend considerable credence to the epidemiological findings that reduced tar and nicotine content of cigarettes will result in lower lung cancer mortality. More than 900 cases with smoking histories were collected in the 1955-1960 era and from among these cases were matched on sex, smoking habit and in this 5-year age group with cases drawn from among 468 cases collected between 1970-1977. Coded slides were read in random order and the findings of number of cell rows, percent with a typical nuclei, carcinoma in situ and early invasive carcinoma were recorded. The data are being analyzed.

HISTOLOGICAL CLASSIFICATION OF LUNG CANCER IN PERSONS EXPOSED TO ASBESTOS

O. Auerbach, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Senior Medical Investigators Laboratory, *Tremont Ave. & S. Centre St., East Orange, New Jersey* 07019 (D-IARC-79-906)

Studies of uranium miners who died of lung cancer have shown a different pattern of histological types from that in non-miners who die of lung cancer. Although there have been some studies of histological type of lung cancer in asbestos workers, these have been on a small series and not classified by the WHO classification of tumor type. Tissue specimens of lung cancer cases (autopsy and surgical specimens) on all subjects diagnosed with lung cancer in a 13 year period are being collected. Asbestos-exposed and non asbestos-exposed persons will be included in this study. Smoking, occupational and residence histories will be obtained from families of the deceased.

RELATIONSHIP BETWEEN CANCER MORTALITY AND ENVIRONMENTAL FACTORS

P.W. Preuss, State Dept. of Environmental Protection, *P.O. Box 1390, Trenton, New Jersey* 08625 (D-IARC-79-908)

The proposed project will correlate the geographical patterns of cancer mortality with environmental and industrial data in the following manner: (1) Statewide environmental and industrial data will be collected for as far back in time as the sources permit. (2) A list of approximately 600 environmental and industrial variables will be identified to be correlates to the cancer mortality data. (3) These variables will be correlated to the cancer mortality data. The mathematical techniques will include bivariate correlation and factor analysis. Bivariate correlation is a statistical tool for measuring the relationship between two variables. Factor analysis provides a measure of the extent to which groups of different variables correlated. Through the use of these techniques, both individual factors and groups of factors which correlated with cancer mortality will be identified. (4) From these results of the correlation of the 600 variables, a list of those 20 to 40 which correlate most strongly with cancer mortality will be generated. (5) Intensive data searches will be conducted in order to reconstruct a 30 year period of population exposure to the 20 to 40 selected variables. (6) Annual exposure rates will then be correlated to annual mortality data to determine if relationships exist between exposure and mortality. In performing these correlations the 20-30 year latency period for cancer will be considered. (7) A final report will be prepared explaining all findings and recommending future courses of action.

FAMILIAL STUDIES OF CANCER

S. Albert, Michigan Cancer Foundation, Dept. of Biometry & Medical Sociology, *110 E. Warren St., Detroit, Michigan* 48201 (D-IARC-79-878)

A retrospective study of cancer incidence among family members, associations between different forms of cancer and other characteristics of cancer lineages is being conducted. The study group consists of more than 6,000 families of post-partum women who participated in studies of viral-like particles in human milk from 1971-1977. Extensive family histories were obtained from these women in the effort to establish a relationship of the presence of viral-like particles to a family history of cancer. These data have been a valuable resource for epidemiological investigation and are central to several studies.

INVESTIGATION OF HIGH PANCREATIC CANCER RATE IN WESTERN NEBRASKA

E. Mahboubi, University of Nebraska, Medical Center, School of Medicine, Dept. of Epidemiology, *42nd & Dewey Aves., Omaha, Nebraska* 68105 (D-IARC-79-897)

Seventeen cases of pancreatic cancer were diagnosed in less than one year by professionals in the newly staffed Western Nebraska General Hospital of Scottsbluff, Nebraska. The unit serves a population of approximately 60,000 inhabitants. The number of cases constitutes an incidence four times greater than expected. This situation prompted the setting up of a survey to: (1) Confirm the high occurrence of pancreatic cases, (2) study places of birth and residence of cases for the purpose of establishing incidence rates, (3) establish a retrospective case-control study to look for common environmental or cultural factors prevalent among the cases which might be associated with the occurrence of pancreatic cancer in the area, and (4) determine any possible risk factors such as occupational exposure to known carcinogens or any factor suspected to be associated with the cases. There will be at least two controls for each case. Eleven western Nebraska counties, Scottsbluff, Sioux, Dawes, Sheridan, Box, Banner, Morril, Garden, Kimball, Cheyenne and Duel, with a population of 95,000, are included in the study.

THE NURSES HEALTH STUDY

F.E. Speizer, Peter Bent Brigham Hospital, Channing Laboratory, *721 Huntington Ave., Boston, Massachusetts* 02115 (D-IARC-79-872)

The risks of various possible carcinogenic exposures in women have not been well described. This prospective cohort study aims to evaluate cancer morbidity and mortality for a number of exposures including oral contraceptive use, cigarette smoking, and hair dyes. Information has been obtained by mail questionnaire for 123,301 married, female registered nurses, residing in one of 11 larger US states, and listed in the directory of the American Nurses' Association in 1972. Biannual follow-up mailings are being performed in 1978 and 1980 to determine the incidence rates of various cancers in relation to the exposures under investigation. Particlar emphasis is placed on risk factors for the development of breast cancer.

OCCUPATIONAL, ENVIRONMENTAL, AND PERSONAL-HABIT-RELATED DISEASES IN THE GREATER WORCESTER AREA

B.S. Levy, University of Massachusetts, Medical School at Worcester, School of Medicine, Dept. of Family & Community Medicine, *419 Belmont St., Worcester, Massachusetts* 01604 (D-IARC-79-875)

There is increasing evidence that much cancer results from occupational exposures. This case-control interview study aims to identify occupational and other factors related to the development of leukemia and cancers of the lung, urinary bladder, kidney, and larynx. Approximately 300 cancer patients who meet the study criteria are being identified from the cancer registries of the five major hospitals in Worcester, Massachusetts. These criteria include a tissue diagnosis of one of the malignancies under study at one of these hospitals in 1976 or 1977 in patients aged 21 years or older who live in Worcester or one of the immediately adjacent towns. After consent is obtained, these patients are interviewed (or their next of kin, if they are deceased) concerning their occupational, residential, and smoking histories; non-occupational exposures to possibly hazardous substances; family history of cancer; long-term use of medications; and ingestion of coffee and alcohol. An equal number of control subjects are being interviewed. The control subjects are patients at the same hospitals in the same years without a history of any malignancy who have been matched to cancer patients in the study by sex and five year age-group and who live in the same residential area. While the total number of cancer patients and control subjects is relatively small, it is hoped that this study may yield clues for investigation by more specific cohort

studies of workers of the same occupation, in the same industry, or with the same exposure.

HERPESVIRUS HOMINIS TYPE 2 ANTIBODIES IN RELATION TO THE DEVELOPMENT OF CERVICAL NEOPLASIA

L. Johnson, New England Regional Primate Research Center, *1 Pine Hill Dr., Southborough, Massachusetts* 01772 (D-IARC-79-874)

An assay of herpesvirus hominis type 2 hemagglutinating antibodies is being made in sera of patients, before the onset of disease, during stages of cervical neoplasia and after treatment and compared with sera of controls who did not develop cancer. This prospective study is possible because sera were collected at the Boston Hospital for Women from pregnant and postpartum women during the years 1959-1965 in the Collaborative Study of Cerebral Palsy. These same women had Papanicolaou smears taken during the same time period in a study of the histogenesis of cervical neoplasia. A sample group of the women was re-examined for cervical neoplasia and serum was collected during the years 1974-1977.

EVALUATION OF PERIODIC BREAST CANCER SCREENING WITH MAMMOGRAPHY AND CLINICAL EXAMINATION

W. Venet, Health Insurance Plan of Greater New York, Dept. of Research & Statistics, *625 Madison Ave., New York, New York* 10022 (D-IARC-79-956)

This is a randomized trial designed to test whether periodic screening with clinical and mammographic examinations results in a long-term reduction in breast cancer mortality. Linked to this primary objective are several issues of major importance in assessing benefits to be derived from breast cancer screening, e.g., the relative value of the two screening modalities, ages of women to be screened, periodicity of screening, identification of parameters related to development of the disease, and determinations of underlying cause of death. Approximately 62,000 women, aged 40-64 at the time of entry to the study and allocated to either a study or a control group, are under surveillance. Study women were offered screening examinations; of the 65 percent who accepted an initial examination, a large majority had at least one of the three additional screenings at annual intervals. Control women continued to receive their regular medical care. Screening ended in mid-1970, and follow-up on the entire study and control populations for breast cancer cases and death ascertainment continues. The survival status of all known breast cases through December of 1977 has been established, and no one is lost to follow-up. New data support earlier results on screening benefits. At ten years of follow-up from entry, 30 percent differential exists between the total study (screenees and refusers) and control group in breast cancer mortality. The impact of the screening program continues to be confined to women 50 years of age and over with no benefit at ages 40-49. Eight year case fatality rates show similar relationships. The differential between control and study cases is due almost entirely to the low rates among cases detected through screening, with cases detected through mammography alone showing a rate that is exceptionally low. At this point in the study there appears to be strong support for periodic screening at ages 50 years and over with the two modalities.

2.2291,

MORTALITY OF WORKERS EXPOSED TO POLYCHLORINATED BIPHENYLS IN MANUFACTURE OF TRANSFORMERS AND CAPACITORS

I.J. Selikoff, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Community Medicine, *5th Ave. at E. 100th St., New York, New York* 10029 (D-IARC-79-905)

The entire workforce employed 1952-1957 in the largest U.S. facility manufacturing capacitors and transformers has been identified with assistance of the plant's union and management. The plant's operation goes back to 1947 and much information is available concerning polychlorinated biphenyl (PBC) exposure, including the types of PBC used over the years. Estimates are also available concerning the intensity of exposure in the various work positions. Age-, year-, and sex-specific deaths will be calculated for this large cohort, on the basis of both state and local death rate data, as well as data of the U.S. National Office of Vital Statistics. The entire cohort is being traced and the observed deaths will be compared with those estimated. While the duration from onset of exposure is shorter than optimal (being only 25 years in some cases), the information to be obtained will at least give data concerning the short-term mortality experience of a group heavily exposed to this halogenated hydrocarbon.

2.2292,

MORTALITY AMONG AMOSITE ASBESTOS FACTORY WORKERS IN RELATION TO SMOKING HABITS, 1961-1977

I.J. Selikoff, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Community Medicine, *5th Ave. at E. 100th St., New York, New York* 10029 (D-IARC-79-951)

The mortality experience of workers in an amosite asbestos products factory is being reviewed prospectively from 1 July 1961, according to individually ascertained smoking habits. Deaths to 31 December 1977 have been recorded and causes of death, including cancer by specific site, asbestosis and other non-infectious lung disease, ascertained. Calculations include expected and observed deaths for those with a history of cigarette smoking and those who have smoked pipe and/or cigar only. Expected deaths are calculated according to age, year and sex specific death rates for the State of New Jersey, first by cause and then separately calculated in smoking specific categories, utilizing death rates over much of the period in question for similar men in a prospective study, by smoking category, of the American Cancer Society. During the period 1 July 1961-31 December 1977, 311 deaths occurred, including 62 from lung cancer. Observation of the cohort survivors continues.

2.2293,

MORTALITY EXPERIENCE OF SHIP REPAIR WORKERS

I.J. Selikoff, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Community Medicine, *5th Ave. at E. 100th St., New York, New York* 10029 (D-IARC-79-952)

Although it is unlikely that there will be wide use of asbestos in new ship construction in the United States in the future, asbestos already in place in many U.S. and foreign ships promises to pose a hazard as these vessels are submitted for repair, maintenance, modernization and renovation. A cohort of all workers is being established in a major eastern U.S. shipyard which has been engaged entirely in ship repair and maintenance since the late 1930s, including all men and women so employed at some time between 1954 and 1964, for at least five years. The status of these individuals will be ascertained as of January 1, 1979. Cohort members will be categorized by trade and for those who have died, causes of death ascertained. A large proportion of the survivors in 1979 will be clinically examined for stigmata of asbestos-associated disease.

METABOLIC EPIDEMIOLOGY OF COLON CANCER AND BREAST CANCER

E.L. Wynder, American Health Foundation Inc., Dept. of Epidemiology, *320 E. 43rd St., New York, New York* 10017 (D-IARC-79-958)

The primary objective of this investigation is to study the epidemiology of colon cancer cases and controls in a high-risk population (Finland) and a medium-risk population (US), paying special attention to the effect of diet on fecal constituents, and to study the constituents in breast fluid from those population groups. It is planned to continue collecting samples from populations at different risks for colon and breast cancer and analyze them for fecal constituents, hormones, mutagens, and/or other components. Results will be correlated epidemiologically to determine dietary or other associations with population differences.

2.2295,

METABOLIC EPIDEMIOLOGY OF COLON CANCER - STUDIES IN LOW RISK FINISH POPULATION

R.S. Reddy, American Health Foundation Inc., Division of Nutrition, *Hammond House Rd., Valhalla, New York* 10595 (D-IARC-79-966)

Colon cancer incidence data from the Nordic countries show a gradient from rural areas in Northern Finland, increasing from Northern to southern Sweden, with highest incidence being reached in Copenhagen, Denmark. Studies thus far completed indicate that excess dietary fat exerts an effect by altering endogenously produced metabolites such as bile acids which appear to have a promoting effect in colon cancer incidence and that dietary fiber has a protective effect in colon carcinogenesis. Although the total dietary fat intake in rural Kuopio, Finland is similar to countries with a high rate of colon cancer, the crucial difference in dietary intake between Kuopio and USA may relate to dietary fiber. The overall objective of this study is to acquire significant information in the high and low risk populations for development of colon cancer on the role played by dietary components on the etiology of this disease. In order to achieve this objective, feces of healthy controls and patients with colon cancer in Kuopio and Helsinki, Finland, and New York Metropolitan area will be analyzed for bile acids, beta-glucuronidase, 7-alpha-dehydroxylase and mutagens. Dietary intake of fiber and fecal bulk will also be determined in these populations.

2.2296,

ROLE OF DIETARY FACTORS IN CANCER OF THE INTESTINAL TRACT

E.L. Wynder, American Health Foundation Inc., Dept. of Epidemiology, *320 E. 43rd St., New York, New York* 10017 (D-IARC-79-959)

The primary objective is to study the epidemiology of gastrointestinal cancers in a high-risk country for gastric cancer (Yugoslavia) and in a low-risk country (United States). A case-control study will be used to determine whether a diet high in cereals and starches and low in fresh vegetables may be linked to gastric cancer. The study will be conducted in three geographical regions: two areas in Yugoslavia, where a strong intra-country gradient exists, i.e., Panonia (high-risk) and Karst (medium-risk), and New York City. It is also intended to determine whether a diet high in fat and low in fiber may be linked to cancer of the colon, as determined by dietary history in a case-control study. The study is to be conducted in the same three geographical areas. The data will be examined to discover whether any epidemiological differences exist between diffuse and intestinal types of gastric cancer. The association between beer consumption and cancer of the rectum will be tested. Data for this case-control epidemiological study are collected by trained research interviewers and more than 500 cases and 600 controls have been interviewed in the American phase of the study. Data collection will begin in Yugoslavia in late 1978.

2.2297,

EPIDEMIOLOGY OF THE LESS HARMFUL CIGARETTE

E.L. Wynder, American Health Foundation Inc., Dept. of Epidemiology, *320 E. 43rd St., New York, New York* 10017 (D-IARC-79-960)

By means of on-going case-control studies, the investigation (1) monitors the use of cigarettes with differing levels of tar and nicotine by hospitalized patients, and (2) identifies the effects of smoking the 'less harmful cigarette' on the development of a wide variety of diseases. Analysis of 3,716 patients with histologically proven cancer of the lung (Kreyberg I and II), mouth, larynx, esophagus, or bladder and more than 18,000 control patients has been published (Cancer Res., 37:4608-22, 1977). A strong relationship between socio-economic status and tobacco-related cancer is reflected in the smoking habits of different groups. Data from 1,934 white male and female patients with histologically verified cancer of the lung (Kreyberg I) and larynx cancer and matched controls have been analyzed (J. Natl. Cancer Inst., in press). Relative risks for developing either lung or larynx cancer were consistently lower among long-term smokers of filter cigarettes than for non-filtered cigarette smokers, irrespective of quantity smoked and after adjustment for duration of the

smoking habit, inhalation and butt length. Risk of developing either cancer declined with years since ceasing to smoke. The changing smoking habits of women were studied in relation to the pussible interaction between occupational health problems and cigarette smoking faced by an increasing proportion of the female population (Prev. Med., in Press). It was found that more women are beginning to consume daily the same quantities of cigarettes as their male counterparts. More non-smokers are represented in the older than the younger age groups of women, supportive evidence of the national trend of increased smoking among young women. The profile of today's female smokers is that of a young, well-educated, social, employed, career-oriented person. Data continue to be collected in New York City and five other cities across the U.S. towards the goal of identifying risks of disease associated with smoking.

METABOLIC EPIDEMIOLOGY OF COLON CANCER

B.S. Reddy, American Health Foundation Inc., Naylor Dana Inst. for Disease Prevention, *Hammond House Rd., Valhalla, New York* 10595 (D-IARC-79-967)

The distribution of cancer of the colon, particularly its infrequency in Japan, its increase among Japanese immigrants to the United States and the high rate of this disease among North Americans and most Western Europeans, strongly indicates that a dietary factor, mainly high fat and animal protein, is of etiological significance. Preliminary studies in metabolic epidemiology have shown that the dietary composition and intestinal microflora play a significant role in the composition of intraluminal compounds such as cholesterol metabolites and bile acids which can act as co-carcinogens for the colon. The overall objective of the proposed research is to delineate the relationship among dietary components, intraluminal compounds, intestinal microflora and colon cancer in man, and to develop a biochemical and/or a bacterial indicator for colon cancer. In order to elucidate the etiological role of bacterially modified intraluminal compounds on the incidence of colon cancer, feces of high risk and low risk populations, patients with colon cancer, polyps, familial polyposis and ulcerative colitis will be analyzed for cholesterol metabolites, bile acids, tryptophan metabolites, microflora and bacterial beta-glucuronidase and 7-alpha-dehydroxylase activities. From these studies, we wish to develop a biochemical and/or a bacterial indicator which distinguishes low and high risk populations for large bowel cancer.

DATA BANK FOR STUDY OF THE EPIDEMIOLOGY OF CHILDHOOD CANCER

S. Grufferman, Duke University, School of Medicine, Dept. of Pediatrics, *Box 3711, Durham, North Carolina* 27710 (D-IARC-79-976)

The major objective of this study is to learn more about the epidemiology of childhood cancers. A questionnaire will be administered to the parents of all childhood cancer patients seen at the Duke Medical Center and to matched hospital controls with information banked for later case-control studies. The epidemiologic data collected will be used to study the descriptive epidemiology of various childhood tumors (singly and in various groupings) as well as associations with potential antenatal, childhood, familial, and environmental etiologic exposures. Information modules on nutrition and radiographic findings are to be added in the near future.

ASSESSMENT OF PAST DIET IN CANCER EPIDEMIOLOGY

M.A. Ibrahim, University of North Carolina, Chapel Hill Campus, School of Public Health, Dept. of Epidemiology, *Rosenau Hall, 201H, Chapel Hill, North Carolina* 27514 (D-IARC-79-971)

The need for a reliable method of estimating dietary consumption in the past has become critical in case-control epidemiologic studies on the relationship of diet to cancer. The research objective of this study is to estimate the reliability and validity of estimates of past dietary intake which are derived from present diet histories or from retrospective diet histories. A population on which a current diet history was obtained in 1963 is located in Evans County, Georgia. This population is being reinterviewed for their recollections of their diet in 1963, and their current diet in 1977. The validity of the retrospective diet history will be assessed by comparing it to the diet history obtained in 1963. The degree of dietary change in this population in 14 years will be assessed by comparing the 1977 current diet history to the 1963 history. Comparisons will be made of average consumption of specific food items. Correlation coefficients of individual consumptions as reported on the respective surveys will also be calculated. This study will establish quantitative estimates of the validity and reliability of obtaining dietary history, retrospectively. Should these estimates prove low, waste of resources on unreliable studies will be avoided. Should they prove high, studies will not fail to be undertaken because of negative criticism of these methods.

PILOT STUDY OF AMBIENT AIR POLLUTION AND SURVIVAL OF CANCER

G.S. Wilkinson, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., Population Studies Div., *Research Triangle Park, North Carolina* 27709 (D-IARC-79-979)

This study is concerned with analyzing potential relationships between reported levels of air pollution in the ambient air and length of survival for diagnosed cancer patients. Categorical indicators of pollution levels will be derived from data available from the National Aerometric Data Bank. Survival times for patients having histologically confirmed cases of cancer who have been accessioned into the Lakes Area Regional Tumor Registry will be analyzed by life table and other appropriate methods. This investigation will permit preliminary statements about the effect that various concentrations of ambient air pollutants may have upon the length of survival of patients having a serious chronic disease - cancer.

STUDY OF WORKERS IN A SODERBERG ALUMINUM SMELTER

C.R. Buncher, University of Cincinnati, School of Medicine, Dept. of Epidemiology & Biostatistics, *Eden & Bethesda Aves., Cincinnati, Ohio* 45221 (D-IARC-79-988)

Several recent studies have suggested that workers in aluminum smelting are subject to an excess risk of lung cancer and some types of leukemia and lymphoma. The indications are that pot room workers are most subject to the risk. This study of 2,700 workers is a follow-up of previous reports with the purpose of trying to relate specific work assignments in this plant with possible excess cancer risk in an occupational mortality study. Death certificates are being obtained and will be compared by work classification within each department of the production facility. This study is part of a tri-partite research project involving industry, labor unions, and government.

MORBIDITY AND MORTALITY PATTERNS AMONG OCCUPATIONALLY EXPOSED ASBESTOS WORKERS (ABBREV)

R.A. Lemen, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (D-IARC-79-996)

Considerable controversy has arisen concerning the validity of true exposure to chrysotile asbestos and its relative importance in the etiology of mesothelioma. Animal experimental evidence is contradictory. One study indicates that Canadian and Rhodesian chrysotile asbestos is the least carcinogenic fiber for mesothelioma, while another study has shown no fiber difference. This investigation will evaluate the risk of mesothelioma from exposure to chrysotile asbestos. It will also evaluate the usefulness of cross-sectional medical data perimeters as indicators of future asbestos-associated disease, e.g., lung cancer, mesotheliomas, gastrointestinal cancer, etc. A prospective analysis of tobacco usage (smoking of cigarettes, pipes, cigars and tobacco chewing) obtained through cross-sectional medical studies will be evaluated in those workers known to have died as a result of lung cancer, mesothelioma and gastrointestinal cancer.

EPIDEMIOLOGY OF CANCER OF THE PENIS

L. Persky, Case Western Reserve University, School of Medicine, Dept. of Urology, *2109 Adelbert Rd., Cleveland, Ohio* 44106 (D-IARC-79-1013)

Cancer of the penis will be studied in relation to recurrent antecedent surgery and other local irritative factors such as trauma of various sorts, exposure to various synthetic materials and previous infection. Any regional occurrence of cancer will be compared to that of cancer of the penis and the incidence of cancer of the penis will be surveyed for the past year to see if there has been an increasing or decreasing incidence or whether its occurrence is static. Local regional factors, such as industrial toxins, fumes, organic chemical usage and the like will be studied also to see if any relationship between these substances and cancer of the penis can be found.

LONG-TERM STUDY OF MINERS EXPOSED TO RADON-222

E.P. Radford, University of Pittsburgh, Graduate School of Public Health, Dept. of Epidemiology, *4200 5th Ave., Pittsburgh, Pennsylvania* 15260 (D-IARC-79-1033)

Eight 5-year cohorts of underground miners born 1880-1919, who are still living or have died in Malmberget, Sweden, have been followed up to 1976. Exposure doses are calculated from radon-daughter measurements in air and water and from radioactivity in water springs in the mines measured in 1914. Attention has been paid to the different depths of the mine over the years and ventilation in different places of work. substantial number of lung cancer cases have occurred in miners who never smoked or were ex-smokers. A survey of smoking prevalence in

active and retired miners has been done to permit assessment of the role of smoking in relation to radon-daughter exposures in the genesis of bronchial cancer.

ANALYSIS OF MORTALITY PATTERNS IN ALUMINUM REDUCTION PLANTS

H.E. Rockette, University of Pittsburgh, Graduate School of Public Health, Dept. of Biostatistics, *4200 5th Ave., Pittsburgh, Pennsylvania* 15260 (D-IARC-79-1035)

A review of the literature on the health effects of worker exposures in the reduction of aluminum indicates that there may be an excessive incidence of respiratory cancers among workers exposed to high levels of coal pitch volatiles. Furthermore, there may be an excessive incidence of other cancers and of chronic obstructive respiratory disease. The largest study to date was a historical prospective study sponsored by the Aluminum Association. In that study, 23,033 men employed for five years or more during the period 1941-1973 at one of fifteen aluminum reduction plants in the United States were followed up through 1973. The present study will use these records as a data base. The objectives of the new study are as follows: (1) to verify the accuracy of the initial data collection, (2) to obtain job histories and include these in the analysis, (3) to obtain estimates of exposure levels, and (4) to extend the follow-up period through 1977. Mortality patterns of groups of workers with varying levels of exposure and of general populations will be compared.

2.2309,

DYSPLASIA OF GASTRIC MUCOSA

S.C. Ming, Temple University, School of Medicine, Dept. of Pathology, *3322 Broad St., Philadelphia, Pennsylvania* 19122

The objectives of this project are two-fold: (1) Establishment of criteria for grading of gastric dysplasia, and (2) Study of prevalence of gastric dysplasia in different countries. It has long been recognized that certain conditions in the stomach are pre-cancerous. Among them are pernicious anemia, chronic atrophic gastritis, intestinal metaplasia, adenoma, and chronic ulcer. The common anatomical basis for increased cancer incidence in patients with these conditions is dysplasia of the epithelial cells. Study of prevalence of dysplasia is, therefore, important. In spite of this recognition, however, there is the need to establish uniform criteria for making the diagnosis. For this reason the International Study Group on Gastric Cancer has directed members of its pathology panel to establish the criteria. This assignment is in the process of being carried out. Once the criteria are established, they will be used by the group to determine prevalence rate of different grades of gastric dysplasia and to correlate the information with prevalence rates of gastric cancer.

EPIDEMIOLOGY OF CHILDHOOD CANCER

S.L. George, St. Jude Childrens Research Hospital, Biostatistics Section, *332 N. Lauderdale St., P.O. Box 318, Memphis, Tennessee* 38101 (D-IARC-79-1036)

This general study will attempt systematic gathering of data from all children with malignant disease admitted to a large children's research hospital. The overall objectives are to characterize better the features of children with cancer and their families and to search for clues to etiology. Techniques to be used include the following: retrospective review of medical records; questionnaire/interview of families at diagnosis when possible; follow-up interviews and examinations for late effects, up-dates of initial information and progeny of long-term survivors; case-control studies where feasible. Over 300 newly diagnosed patients with cancer are admitted each year, mostly from the immediately surrounding, largely rural area. Areas to be systematically covered for all families include: socio-economic/occupational history, exposure to known carcinogens/pathogens (including ionizing radiation), previous diseases, other environmental factors and host factors (familial cancer, congenital abnormalities, etc.). An initial case-control study of children with colorectal cancer, using neighborhood controls has begun.

MORTALITY FOLLOW-UP STUDIES OF WORKERS EXPOSED TO CHLORINATED SOLVENTS

P.A. Buffler, University of Texas, Medical Branch at Galveston, School of Medicine, Dept. of Preventive Medicine & Community Health, *300 University Blvd., Galveston, Texas* 77550 (D-IARC-79-1039)

Seven chlorinated solvents (vinyl chloride monomer, 1,4-dioxane, methylene chloride, trichlorethylene, perchloroethylene, methyl chloroform and ethylene dichloride) have been identified as compounds of interest for mortality and morbidity investigations of occupational exposure. Personnel and medical records of a major chemical company dating back to 1940 have been used for these studies. The cohorts of employees exposed to each of these solvents during the production process or as consumers of the product in subsequent production are being identified. A within-industry comparison group of non-exposed employees has been identified and the mortality follow-up completed. The study of 1,4-dioxane (165) has been completed and was published (April 1978 - Journal of Occupational Medicine). The study of 464 vinyl chloride monomer-exposed workers has just been submitted for publication. The study of methylene chloride-exposed workers is nearing completion. No excess of cancer deaths was observed among the 1,4-dioxane-exposed group, although the cohort size was too small for any conclusive statements. An excess of respiratory cancer was noted among the VCM-exposed workers, particulary at higher levels of exposure for those with a longer duration of exposure.

EPIDEMIOLOGY OF PRIMARY LIVER CANCER IN SELECTED COUNTIES OF TEXAS

P.A. Buffler, University of Texas, Medical Branch at Galveston, School of Medicine, Dept. of Preventive Medicine & Community Health, *300 University Blvd., Galveston, Texas* 77550 (D-IARC-79-1040)

Several counties in Texas have been identified as having high rates of primary liver cancer (PLC), approximately three times as great as that reported for the total U.S. Three of these 'high rate' counties are associated with heavy chemical and petrochemical industry concentrations. In 1977 a retrospective study of all liver cancer deaths occurring in Brazoria County, Texas, during the interval 1960-75 was conducted to determine if the proportion of chemical workers is higher among persons dying from primary liver cancer than among persons dying from non-malignant diseases. Occupational histories were obtained from participating industries for all cancer deaths and controls. Clinical and histopathologic review of all deaths due to PLC and other liver-related diseases is being conducted. The study is currently being extended to the two larger counties, Orange and Jefferson, which also have a heavy concentration of chemical and petrochemical plants. Additional studies are anticipated in Texas counties having high rates of PLC which are nonindustrialized but where exposure to hepatitis B, insecticides or aflatoxin B may be involved.

IMPACT OF CANCER ON TEXAS - AN EPIDEMIOLOGICAL ANALYSIS

V.F. Guinee, University of Texas, University of Texas System Cancer Center, M.D. Anderson Hospital & Tumor Inst., Dept. of Epidemiology, *c/o Texas Medical Ctr., Houston, Texas* 77030 (D-IARC-79-1047)

In the first phase of the analysis, descriptive epidemiological studies are being based on cancer mortality (1969-76) as reported to the State on death certificates and county population data from the 1970 census. Age-adjusted rates for each county and Health Services Areas have been calculated. Total cancer mortality and the mortality from ten major cancer sites have been detailed in a publication 'Impact of Cancer on Texas'. Future analyses will include geographical and ethnic patterns, as well as in-depth studies of populations with apparent high and low risks of developing cancer. New mortality data will be incorporated in the computerized data base as they become available.

REGISTRY FOR CARCINOMA IN SITU OF THE VULVA

E. Friedrich, Medical College of Wisconsin, School of Medicine, Dept. of Gynecology & Obstetrics, *561 N. 15th St., Milwaukee, Wisconsin* 53233 (D-IARC-79-1075)

The registry operates under the auspices of the International Society for Study of Vulvar Disease. In accordance with the new nomenclature, this includes cases of squamous cell carcinoma in situ (formerly Bowen's disease, erythroplasia of Queyrat and carcinoma simplex) as well as cases of vulvar Paget's disease. The purpose of the Registry is to accumulate epidemiological and histological data in order to define the biological characteristics of the disease, determine its frequency and identify the high risk patient. Histological slides and completed registry forms are kept in a central file and the data are compiled at regular intervals. Over 100 cases have been collected since the Registry opened. Physicians desiring to register cases or obtain additional information are asked to contact Dr. Peter J. Lynch, Professor or Dermatology, University of Arizona Medical Center, Tucson, AZ 85724, or Dr. Raymond H. Kaufmann, Professor and Chairman, Baylor College of Medicine, Texas Medical Center, Houston, TX 77025.

EPIDEMIOLOGICAL STUDIES OF CANCER

J.F. Fraumeni, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Epidemiology Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205 (D-IARC-79-848)

The Environmental Epidemiology Branch of the National Cancer Institute of the United States conducts and coordinates a variety of studies in cancer epidemiology. Some of these are outlined below. (1) Following a county-by-county mapping of cancer mortality, several correlation and analytical studies are underway to help identify the environmental determinants of cancer in high-risk communities. (2) A program of occupational studies searches for cancer hazards associated with various industries, for example, petrochemicals, pharmaceuticals, printing, leather, dry-cleaning, automobile, pest control and metal smelters. (3) The carcinogenic effects of drugs are evaluated by studies of cancer risk following use of exogenous estrogens, alkylating agents, and immunosuppressive therapy. (4) Evaluation of radiation-induced cancer involves surveys of women receiving repeated chest fluoroscopy for tuberculosis, survivors of the atomic bomb, and recipients of radioactive iodine for diagnostic or therapeutic reasons. (5) Mechanisms of host susceptibility to cancer are clarified by the identification of high-risk disorders (e.g. primary and acquired defects of immunity) and by multi-disciplinary studies of cancer-prone families. (6) Studies are carried out to evaluate the effects of pollutants in the general environment, for example, halogenated hydrocarbons in drinking water. (7) Studies of cancer in domestic animals are conducted in hopes of identifying animal counterparts to human neoplasia. (8) Emphasis is given to multi-disciplinary collaboration with experimentalists to elucidate risk factors (e.g. nutritional, hormonal, viral, genetic) that require laboratory measures.

THE ETIOLOGY OF ALCOHOLISM - A LONGITUDINAL STUDY

J.A. Carpenter, Rutgers the State University of New Jersey, New Brunswick Campus, Center for Alcohol Studies, *Old Queens Bldg., New Brunswick, New Jersey* 08903 (41-AA-25)

PURPOSE: To elucidate the social cultural, psychic, and somatic characteristics that are predictive of a heightened risk of developing problem drinking or alcoholism.

SUBJECTS: 5,230 girls and boys, ages 13 (2700), 16 (750), 22 (750), and 25 (300), born in New Jersey. The subjects will be re-examined at 3- and 6-year intervals, depending on age.

METHODS: The study (designed to run 30 years), formally described as a replicated cross-sectional, multiple cohort longitudinal study, will examine individuals of different birthdates at frequent intervals following the principles first described in the classic work of Schaie (1965). Data will be gathered from four areas: sociology, physiology-biochemistry, personality-behavior, and perception-cognition. Scientists from these discipline areas and from life span developmental psychology and statistics will collaborate in the program. The Eagleton Institute of Politics, Rutgers University will obtain the samples of subjects to be used in the study through telephone contacts. In a parallel study, an anonymous matching survey will obtain information on drinking, socioeconomic status, geographic representativeness, religion, etc. of a random sample of non-participants. The main sample will be compared to the results of the survey to ensure proper representativeness despite refusals to participate. To maintain the interest of the subjects and to ensure their continued participation over the years, subjects will be paid for their participation. They will be contacted annually and brief progress reports will be elicited.

COLLABORATIVE STUDIES IN CEREBRAL PALSY AND OTHER NEUROLOGICAL AND SENSORY DISORDERS OF INFANCY AND CHILDHOOD

J.S. Drage, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, *9000 Rockville Pike, Bethesda, Maryland* 20205 (41-AA-11)

PURPOSE: The Collaborative Perinatal Project (CPP) is a longitudinal multidisciplinary research effort which seeks leads to the etiologies of cerebral palsy, mental retardation, learning disorders, congenital malformations, minimal brain dysfunction, convulsive disorders, and communicative disorders through studies which relate the events, conditions, and abnormalities of pregnancy, labor, and delivery to the neurological and mental development of the children of these pregnancies.

SUBJECTS: During a period from 1959 through 1966, detailed research data were obtained from 50,000 women during pregnancy, labor, and delivery. The children born to these 50,000 women during their participation in the CPP have been examined at specific intervals up to the child's 8th birthday to identify abnormal conditions which might limit the child's ability to reach maximum developmental potential.

METHODS: A comprehensive analysis of the data will investigate the complex interactions between the child's condition and the antecedent factors which may have contributed to the condition. The analysis of this data is underway within the National Institutes of Health, within other governmental agencies, and under contract with teams of investigators at medical centers outside of government. The Perinatal Research Branch and the National Institute of Neurological and Communicative Disorders and Stroke have the responsibility for monitoring, coordinating, and administering the overall research effort. The goal of this effort is to make a series of publications available to the research community and the general public. The projected completion of this analysis is June 30, 1976. The data for the CPP were collected at 12 major medical centers in the United States.

CHILD HEALTH AND DEVELOPMENT STUDIES

B.J. Van den Berg, University of California, Berkeley Campus, School of Public Health, *Berkeley, California* 94720 (41-AA-3)

PURPOSE: To investigate the relationships of biologic, genetic, and medical and environmental factors in the parents (including events in pregnancy, labor and delivery) to the normal and abnormal developmnt of the offspring; and to investigate the relationships of these factors to pregnancy loss in the form of early fetal death, perinatal mortality, infant and childhood mortality, and to incidence of congenital anomalies, to growth and morbidity patterns in infancy and childhood, and to cognitive attainment, behavioral development, and physical characteristics at ages 5 and 10 years.

SUBJECTS: Members of the Kaiser Foundation Health Plan (a prepaid medical health plan) who reside in the San Francisco-East Bay Area.

METHODS: The method of study is longitudinal for both mother and child. In addition to information obtained specifically for the studies, the medical records for the gravida and child provided information on illnesses, injuries, and drugs. A special interview and developmental examination were given the child on his 5th birthday and to a large sample of children when they were ages 9 to 11. These include vision, hearing, speech, and tests of cognitive ability. It is planned to extend the observations with a follow-up examination of a subcohort of about 2,000 mothers and their children when the latter are about 16 years old. An epidemiological research project is in process, aimed at the identification of precursory factors for high blood pressure in young persons.

THE BERKELEY, CALIFORNIA GROWTH STUDY

D.H. Eichorn, University of California, Berkeley Campus, Inst. of Human Development, *1203 Tolman Hall, Berkeley, California* 94720 (41-AA-4)

PURPOSE: To study the mental and physical growth of normally healthy persons from birth to the present.

SUBJECTS: 60 full-term, healthy newborns, born in Berkeley hospitals from 1928 to 1929 of white, English-speaking parents; and 140 offspring of these subjects, ages birth to 20, seen irregularly.

METHODS: The same data, appropriate for age, were collected for the subjects and their offspring. Beginning in the first week of life, tests of mental and motor development, pediatric examinations, and interviews were conducted at frequent intervals during growth. At all visits, inquiries were made concerning current health and recent illnesses. Anthropometrics, body photographs, and skeletal X-rays were taken at most ages. Socioeconomic data were collected. Studies of the physical aspects of growth include analyses that compare health histories with physical growth and with skeletal maturation. Emotional and other personality variables are being studied for consistency, and in various interrelations with maternal behavior in infancy, birth histories, socioeconomic status, and intellectual and physical growth.

LONGITUDINAL GROWTH STUDIES OF CHILDREN WITH CRANIOFACIAL BIRTH DEFECTS

S. Pruzansky, University of Illinois, Medical Center at Chicago, Abraham Lincoln School of Medicine, Dept. of Pediatrics, *1853 W. Polk St., Box 6998, Chicago, Illinois* 60680 (41-AA-9)

PURPOSE: To study the epidemiology, genetics, morphology, physiology, and postnatal development of children; and to plot the natural history of children with craniofacial birth defects.

SUBJECTS: Over 3,000 subjects, males and females, from infancy to adulthood.

METHODS: The subjects were initially studied as infants. Procedures included roentegenocephalometry, tomography, dental casts, and photographs. Speech and hearing, psychosocial, and pediatric evaluations supplied additional information.

FINDINGS: Patterns of growth have been delineated that are useful in clinical management. Some conditions have been shown to get worse; some show spontaneous improvement; and others remain unchanged. Syndrome-specific cranial morphologies have been described and genetic significance has been described.

CYTOGENETICS OF MENTAL RETARDATION

P.A. Jacobs, University of Hawaii System, Manoa Campus, John A. Burns School of Medicine, Dept. of Anatomy & Reproductive Biology, *2444 Dole St., Pacific Biomedical Res. Ctr., Honolulu, Hawaii* 96822 (41-HB-1)

PURPOSE: To determine the frequency of chromosome abnormalities in a population of unselected mental retardates; and to investigate (1) the contribution of chromosome abnormalities detectable, using banding techniques, to the etiology of mental retardation; and (2) the incidence of heteromorphisms in the various racial groups in Hawaii.

SUBJECTS: To date: 700 moderately to profoundly mentally retarded Hawaiian subjects, ages 0 to 29.

METHODS: Patients from the state institution for the mentally retarded and private educational facilities are surveyed. After a small blood sample is obtained, the chromosomes are examined on the microscope using modern banding techniques. Results agreed upon by at least two observers are recorded. All cytogenetic results and patient data are entered on the computer for statistical analysis.

FINDINGS: Of the 700 children examined, detectable chromosome abnormalities have been found to be the reason for retardation in 12%.

BIBLIOGRAPHIC REFERENCES: Jacobs, P. A. et al. A cytogenetic survey of an institution for the mentally retarded: 1. Chromosome abnormalities. Clinical Genetics, 1978, 13, 37-60.

MUSCATINE FAMILY STUDIES PROGRAM

H.G. Schrott, University of Iowa, School of Medicine, Dept. of Medicine, *Jessup Hall, Iowa City, Iowa* 52240 (41-GA-1)

PURPOSE: To study the familial aggregation and inheritance of coronary risk factors.

SUBJECTS: Between 4,000 and 5,000 family members of school children who have different blood lipid levels or different blood pressures.

METHODS: The researcher used the family study method to examine all first and second degree relatives.

FINDNGS: Data indicate increased coronary mortality in relatives of hypercholesterolemic school children and no increased coronary mortality in relatives of hypertriglyceridemic children.

SEXUAL ABUSE AND ESCAPE/AGGRESSION INCIDENCE IN JUVENILE DELINQUENTS

J.W. Reich, Arizona State University, Graduate School, Dept. of Psychology, *Tempe, Arizona* 85281 (41-KE-3)

PURPOSE: To determine if children who earlier were reported for sexual abuse in later life develop juvenile delinquency crime patterns of aggressiveness or patterns of escape and runaway infractions.

SUBJECTS: Sample 1: 20 girls and boys, ages 10 to 15, who had been reported to authorities for being sexually abused. Sample 2: 747 juvenile delinquents, ages 10 to 15, who had not been reported for either sexual or physical abuse.

METHODS: To test for the accuracy of the apparently wide-spread notion that abuse (both physical and sexual) leads to later aggressiveness in children, two samples of juvenile delinquents were developed. The experimental sample was composed of 153 children referred to the Arizona Department of Economic Security Child Protective Services office for abuse. Of these children, 20 had been referred for sexual abuse. This set of cases was then compared to the juvenile files of the Maricopa County (Arizona) Juvenile Court Center, and patterns were determined of juvenile crimes for which the children had been arrested. This sample was compared to the crime patterns of a random sample of 747 juveniles for whom there had been no earlier report of abuse. The crime patterns were based on the assumption of psychologically important differences between juvenile crimes involving aggression (fighting, aggravated assault, disturbing the peace, etc.) and so-called escape crimes (runaway, missing juvenile, truancy). The former were defined for this project as indicating a hostile and basically antiperson psychological state; whereas, the escape crimes were defined as nonaggressive and asocial in their psychological origins. Chi-square tests were performed to determine the significance of the differences in crime frequencies between the experimental (sexual abuse) sample and the control (nonabused) sample for aggressive and escape crimes.

FINDINGS: The results indicated that sexually abused children had a significantly higher frequency of escape crimes than did the controls and did not differ from controls on aggressive crimes. The data thus offer no support to the belief that sexual abuse leads to more aggressive behavior. The data do support the prediction that sexual abuse leads to later asocial behavior in the form of escape and runaway infractions.(Text Truncated - Exceeds Capacity)

CHILD FATALITIES STUDY

M. Lauderdale, University of Texas, Austin Campus, School of Social Work, Dept. of Social Work, *200 W. 21st, Austin, Texas* 78712 (41-RH-4)

PURPOSE: To develop client profiles and systems information relating to nonaccidental child fatalities in Texas from 1974 to 1976.

SUBJECTS: 271 children and data relating to their families with comparative cohort of 5,000 children where abuse and neglect have been substantiated but have not resulted in child fatility.

METHODS: Information was analyzed from the Texas Central Registry and from case records and is being analyzed from personal interviews with workers. The focus will be on developing individual profiles of parents and also on analysis of systems aspects.

HEALTH OF CHILDREN IN HAWAII

T.A. Burch, State Research & Statistics Office, *1250 Punchbowl St., Honolulu, Hawaii* 96782 (41-SA-4)

PURPOSE: To answer questions about the health of children in Hawaii; and to evaluate health programs.

SUBJECTS: A random sample of households throughout the State of Hawaii consisting of approximately 6,000 households per year, and all vital records in the state.

METHODS: Cross-tabulations were conducted by age, sex, race, and other parameters with various health indices, conditions, disabilities, socioeconomic factors, etc. The data were evaluated by various statistical methods for assessing and evaluating the health status, health problems, and health trends in various subgroups of the populations.

LONGITUDINAL COMMUNITY WIDE STUDIES OF ANTECEDENTS AND CURRENT FACTORS ASSOCIATED WITH CHILD AND ADOLESCENT MENTAL HEALTH AND DRUG USE

S.G. Kellam, University of Chicago, School of Medicine, Dept. of Psychiatry, *5801 S. Ellis Ave., Chicago, Illinois* 60637 (41-SG-1)

PURPOSE: To determine how early social adaptation and psychological well-being relate to each other, in the context of the family and classroom, to inhibit or enhance adolescent mental health and drug use from the beginning of school or midadolescence.

SUBJECTS: Total populations of children form the Woodlawn area of Chicago in 1st grade during the 1960's; and a 10-year follow-up of the entire 1966-67 sample of 1st grade children and their families (N equals 1,242).

METHODS: Systematic, quantified measures were used to assess (1) the child's social adaptational status in 1st grade, in 3rd grade, and at age 16 to 17; which included teacher observations, readiness, and intelligence test scores and grades; (2) mother's reports of her child's social development in 1st grade and at age 16 to 17; and (3) the child's drug use, antisocial behavior, and the extent and quality of social involvement. Extensive data on family characteristics were obtained in 1st grade and at the follow-up. These data concerned structure, social interaction, and psychological atmosphere aspects of the family.

FINDINGS: There appear to be strong antecedents in 1st grade of teen-age drug use as well as psychological well-being. These patterns are much clearer for boys than for girls. Shyness and aggressiveness in 1st grade, both coupled almost always with learning problems, are associated in quite contrasting fashion to drug use in adolescence. Shy 1st graders grow up to use drugs much less, while aggressive 1st graders are the heaviest drug users 10 years later. Learning problems in 1st grade, with or without shyness or aggressiveness, were associated with lower psychological well-being in the teen-age years. Again, these results hold mainly for boys. Girls appear to have much less continuity over these years and a much less clear pattern of their antecedents of adolescent outcomes.

CHILDHOOD LEAD, PYRIMIDINES, AND METABOLIC DEBRIS

C.R. Angle, University of Nebraska, Medical Center, School of Medicine, Dept. of Pediatrics, *42nd & Dewey Aves., Omaha, Nebraska* 68105 (41-SH-2)

PURPOSE: To define, in a large-scale childhood lead poisoning program, the biochemical significance of the inhibitory effect of lead on red cell pyrimidine 5'-nucleotidase (P5N) and its molecular relevance to globin synthesis.

SUBJECTS: Preschool girls and boys, ages 2 to 5, identified and followed in the Omaha Childhood Lead Poison Program.

METHODS: The correlation of blood lead levels of children with red cell P5N and cytidine is being assessed. An in vitro assay of the effect of cytidine and P5N deficiency on alpha and beta chain globin synthesis with be conducted.

STUDY OF CANCER PATTERNS AT BARAGWANATH HOSPITAL FOR BLACKS, JOHANNESBURG

J.S. Harington, National Cancer Assn. of South Africa, Cancer Research Unit, *9 Jubilee Rd., Johannesburg 2000, Transvaal, South Africa* (D-IARC-78-429)

In the Baragwanath Hospital survey, material on black cancer cases admitted to Baragwanath Hospital, Johannesburg, over the years 1948-64 was analysed, and it was possible to obtain a useful incidence rate, a ratio study and a tribal analysis for purposes of comparison. The incidence rate, when compared to an earlier Johannesburg survey, showed a rise in oesophageal cancers for males and females. Both lung and prostate cancers showed rising rates in the men, while the female breast and cervix cancer rates remained relatively constant. Liver cancers had decreased in both sexes. This study is being continued and brought up to date.

EPIDEMIOLOGICAL STUDY OF CANCER AMONGST EPILEPTICS ON ANTI-CONVULSANT DRUGS

S.J. White, University of London, University College Hospital Medical School, *University St., London WC1E 6JJ, England, United Kingdom* (D-IARC-79-651)

Animal studies have suggested that epileptics taking phenobarbitone and other anticonvulsant drugs may be less likely to develop cancers of various sites than the general population. By studying the causes of death amongst epileptics it is hoped to assess whether or not there is evidence for this hypothesis. Two groups of epileptics are being looked at. The first consists of a hospital-based cohort of long-stay patients, and the second of less severe epileptics who are not admitted to hospital. For the first cohort it has not been possible to obtain comparable control group but a control group of persons with limb disabilities has been taken for the second cohort. Information is recorded on age, date of the first fit, and, where possible, type and duration of anticonvulsant drug treatment. When the subject dies, the cause of death is noted from the Cause of Death Notification received by the National Health Service Registry. For the first cohort, the deaths from cancer of various sites are compared with the corresponding rates for the general population, and for the second cohort with those for the control group.

THE MORTALITY FROM LEUKEMIA AND OTHER CANCERS AMONG PATIENTS WITH DOWN'S SYNDROME (MONGOLS)

W.W. Holland, St. Thomas Hospital Medical School, Dept. of Community Health, *60 Sancroft St., London SE11 5NG, England, United Kingdom* (D-IARC-78-564)

An association between Down's Syndrome and increased mortality due to leukemia has been established over the last two decades. The hypothesis that the additional acrocentric chromosome in those with this disorder may also predispose to cancers other than leukemia has been impossible to test because of insufficient mortality data relevant to older age groups. The present study was designed to assess the mortality of older patients with Down's Syndrome in whom cancers other than leukemia would be expected to assume a more important role. Between 1945 and 1967, 2556 patients with Down's Syndrome were studied. The groups was drawn from patients attending the Hospital for Sick Children, Great Ormond Street, in-patients of twelve mental subnormality hospitals, and patients in the care of the former Middlesex County Council. The relative risk of mortality from leukemia and other cancers among those with Down's Syndrome was determined by comparing the number of deaths attributed to these causes in the defined group with the expected number of deaths from these causes in a sex and age equivalent group of the general population of England and Wales. While an excess mortality from leukemia was observed in the group with Down's Syndrome, there was also a significantly higher-than-expected number of deaths due to cancers other than leukemia in males aged 40 years and over (p less than 0.05). Three of the eleven deaths in males due to cancers were due to tumors of the testes, which is 40 times more common than in the general male population (p less than 0.001).

PRENATAL EVENTS AND CHILDHOOD CANCER

N. Munoz, Centre International de Recherche sur le Cancer, Interdisciplinary Programme & International Liaison, *150 Cours Albert Thomas, 69372 Lyon Cedex 2, France* (D-IARC-79-178)

This programme uses material from established prospective studies to assess the role of prenatal events in the incidence of congenital malformations. The Oxford study was started in 1972; by December 1977 cohort of 18,000 had been assembled. The pregnancy records in this study contain information on illnesses during pregnancy and on exposure to drugs and chemicals; two or more antenatal serum samples and one postnatal sample were collected for each woman admitted to the study. The Hungarian study dates from 1975 and now consists of the records of 12,500 pregnant women. In this study antenatal specimens will also be available, in addition to the pregnancy record. The children born to women participating in either of these studies are being followed to identify those with congenital malformations or cancer. The occurrence of these diseases will be correlated with specific intrauterine exposures recorded in the pregnancy records, and the serum specimens and controls will be used appropriately.

2.2339,

ORAL FOCAL EPITHELIAL HYPERPLASIA (ABBREV)

F. Praetorius, Kobenhavns Tandlaegehojskole, Dept. of Oral Pathology, *Universitetsparken 4, DK2100 Copenhagen OE, Denmark* (D-IARC-79-135)

Oral focal epithelial hyperplasia is widespread among Eskimos and Amerindians, but rare among Caucasians (Europides). In Greenlanders there seems to be a direct relationship between the prevalences found and the degree of mixture of the population with Caucasians. This may be due to an influence of a genetic factor, and serological studies are, therefore, performed. Histology and electron microscopy seem to indicate a viral etiology of the disease; the size and morphology of the virus-like particles correspond to what has been described in verruca, condylomata, and in oral papillomatosis in dogs and rabbits. Pilot studies with immunofluorescence technique have shown that the patients with focal epithelial hyperplasia produce antibodies against an antigen in the affected cells. It is likely that the disease is contagious. Epidemiological studies have been performed on 3,500 persons in Greenland and on population groups of Greenlanders and Danes in Denmark. Follow-up studies are undertaken in Greenland. Electronic data analysis of the collected material is performed in collaboration with J.E. Bearman. Blood group type studies are done on saliva samples from the same persons and are performed in collaboration with Dr. H. Guertler, Copenhagen. Family studies are carried out in collaboration with Dr. R. Gessain, Paris, who is in possession of records of the entire Eskimo population of the east coast of Greenland, dating back to about 1820. Biopsies from Greenland are studied histologically and ultrastructurally; immunofluorescence studies are also carried out. The electron microscopic studies are performed in collaboration with Dr. O.Fejerskov, Arhus, Denmark. Tissue culture studies are also performed.

ASSESSMENT OF THE CARCINOGENICITY OF ISONIAZID IN PATIENTS WITH PULMONARY TUBERCULOSIS

H. Stott, Medical Research Council, Tuberculosis & Chest Disease Unit, *Fulham Rd., c/o Brompton Hospital, London SW3 6HP, England, United Kingdom* (D-IARC-79-646)

There is evidence that isoniazid in high dosage can induce neoplasms of the lung and lymph nodes and sometimes leukaemia. This study aims to assess the carcinogenicity of isoniazid by the follow-up of nearly 4,000 adult tuberculous patients admitted to two hospitals from 1950 to 1957. Details of the dosage of isoniazid received by the patients (including the daily dosage and duration) have been reported, as well as other antituberculous drugs received, a crude estimate of exposure to ionising radiation and of the smoking history in males. Reports of deaths among the population are obtained from the Office of Population Censuses and Surveys for England and Wales (as well as from replies to routine postal questionnaires) and the mortality in these patients is compared with that expected in the general population in England and Wales of the same age, sex and occurring during the same period. The follow-up at present ranges from 16 to 23 years after entry to the study and in view of the long induction time between first exposure to a carcinogen and the development of cancer, it is being continued indefinitely.

TROPHOBLASTIC DISEASE IN SINGAPORE

S. Shanmugaratnam, Kandang Kerbau Hospital, University Unit, *Hampshire Rd., Singapore 8, Singapore* (D-IARC-78-423)

Since 1957, all cases of hydatidiform mole have been followed up in a special clinic in this unit. The risk of developing a malignant form of trophoblastic disease in this unit is about 15%. Various different types of treatment have been used in the treatment of these cases including surgial excision of single pulmonary metastases. Chemotherapy is the main line of treatment, and a fixed protocol is followed. Up to now, over 750 cases have been documented and followed up from time to time. A review is made so that the management may be altered to give the best possible treatment to the patients. Hence there is no fixed duration to the study. Although most of the work done has been clinically oriented, some of our publications have correlated the incidence with climatic conditions, time of year, ethnic group, blood groups and other epidemiologic parameters.

POONA CANCER REGISTRY

U. Shah, University of Poona, B.J. Medical College, Dept. of Social & Preventive Medicine, *Poona 411001, Maharashtra, India* (D-IARC-79-279)

The purpose of this study is to obtain reliable morbidity data on cancer from a precisely defined urban area (Poona) with a population of about 1-2 million. Apart from Bombay no such study has been carried out in India before. All institutions in Poona, medical profession, hospitals and Poona municipal corporation and authorities of cantonments cooperate fully. Staff, field workers and statistical laboratory are provided. The Poona Cancer registry has continued its work since 1973. The report for the first three years will soon be published. A rural cancer registry has been started at Sirur District, Poona, Maharashtra State. Also population-based this registry covers a defined population of 43,000 persons living in 22 villages.

RESEARCH INTO OCCULT CARCINOMA OF THE THYROID GLAND IN AUTOPSY MATERIAL AND SURGICAL SPECIMENS

F. Fialho, Hospital de Clinicas Gaffree e Guinle - FEFIERJ, Laboratorio de Anatomia Patologica, *Rua Marques de Abrantes #219, Apt. 302, Rio de Janeiro, Brazil*

OBJECTIVE: Research into occult carcinomas of the thyroid gland with a view to the study of its pathologic anatomy, its incidence and its biology.

METHOD: Research will be performed on autopsy material and on surgical specimens, correlating the findings with the clinical protocols.

PROGRESS: Material from 400 autopsies has already been reviewed and an incidence of 2.7% has been found. In 90 surgical specimens, 15 occult carcinomas were found.

In the cases diagnosed through the study of surgical specimens, the association with other pathologic conditions of the thyroid gland is investigated. Currently, cytologic studies are also performed.

EPIDEMIOLOGIC INVESTIGATION AND CASE-CONTROL STUDIES OF BLADDER CANCER PATIENTS

W. Fokkens, Rotterdamsch Radiotherapeutisch Instituut, Dept. of Documentation & Epidemiology, *Grene Hilledijk 301, Box 5201, 3075 EA Rotterdam, Netherlands* (D-IARC-79-416)

All bladder cancer patients treated at the Rotterdam Radiotherapy Institute are interviewed about their occupational history and about other suspect factors such as smoking and phenacetin use. Since March 1977, in collaboration with Health Insurance Unions, interviews are also conducted on bladder cancer patients below 60 years of age living outside the Rotterdam region.

ENDOMETRIAL ADENOCARCINOMA-ASSOCIATED OVARIAN PATHOLOGY

G. Reeves, Universidad Nacional de Rosario, Facultad de Ciencias Medicas, Catedra de Patologia, *Santa Fe 3100, 2000 Rosario, Argentina*

OBJECTIVES: To determine the frequency of morphologic abnormalities of the ovary in patients with endometrial adenocarcinoma (EAC). To study the nature of the ovarian pathology (OP) found. To correlate these findings with other clinical and pathologic variables in order to detect the importance of OP in the induction, diagnosis, treatment and outcome of EAC. To determine, if possible, better ways of early diagnosis and treatment of patients with OP causally related to the appearance of EAC.

METHODS: The material will be obtained from private and welfare hospitals of the city of Rosario with a stable population of 1 million people and through gynecologists and pathologists affiliated to GEO. The clinical records, the pathology reports and the available pathology slides, paraffin blocks and/or wet tissue stock from patients that have undergone adnexo-hysterectomy as part of the treatment for EAC, will be critically reviewed and reclassified when indicated. Control cases will be provided when possible for the same age range, socioeconomic status and institution of origin.

PROGRESS REPORT: A test study has already been conducted involving 308 study and 387 control cases. No efforts were made to obtain additional information and the clinical and pathologic diagnoses made in different institutions, by different physicians and within a period from 5 to 20 years were accepted without review. The incidence of OP in EAC cases was double that of controls and was twice as frequent in people under 41 and above 69 years of age. Sterility was high in the EAC group and its frequency was double that found in EAC cases under 41 years. Non-sterile patients under 41 years had a lower number of pregnancies and offspring and low fertility patients - sterile or with only one pregnancy - contributed the gross of the young population with EAC and were more frequently obese. The presence of OP, in general, tended to produce an early diagnosis of EAC and an early stage of neoplastic development. These findings suggest that OP frequently precedes the development of EAC and is probably operative in its induction. The chief ovarian abnormality is a primary or secondary hyperplasia of the ovarian stroma and, to a lesser extent, the existence of a chronic status of impaired ovulation or functioning tumor.

BCG VACCINATION AND LEUKEMIA

L. Katz, Israel Center for Registration of Cancer & Allied Diseases, *18 20 King David St., Jerusalem, Israel*

The possibility that the reported non-specific immunity conferred by BCG may have some influence in the prevention of leukemia in children is being investigated. In Israel a unique opportunity presents itself for studying the incidence of leukemia in BCG vaccinated children and non-vaccinated control group as since 1955 routine BCG vaccination of newborns has been carried out in all maternity wards in Israel - with the exception of the Jerusalem hospitals, where it was never introduced. The incidence of leukemia in children born in Israel since 1955, diagnosed from 1960 onwards (foundation of the Israel Cancer Registry) and up to the age of ten will be studied. 263 cases of leukemia in children have been identified. Their places of birth are now being ascertained.

LONG-TERM TRENDS IN STOMACH CANCER MORTALITY AMONG KRAKOW REGION INHABITANTS

W. Jedrychowski, Akademia Medyczna W Krakowie, Inst. of Social Medicine, Dept. of Epidemiology, *Ul. Kopernika 7, 31034 Cracow, Poland* (D-IARC-79-453)

The aim of the study is to compare mortality from malignant gastrointestinal neoplasms in groups of inhabitants living in four city districts differing in their demographical features and nutritional habits. The analysis is based on death certificates and interviews on dietary habits carried out in representative samples of the inhabitants. The results of a preliminary study based on a 1974 survey show higher mortality rates for all causes, and for gastrointestinal neoplasms in particular, in the center of the city, with the exception of mortality due the stomach cancer in women, than among the suburban population. Mortality rates due to gastrointestinal neoplasms of stomach, liver, gallbladder and pancreas, colon and rectum were also high in men living in the newly developed part of the city. The differences in the consumption patterns of basic food products failed to explain fully the observed divergence between the mortality rates. However, the higher mortality rates in the center could be explained to some extent by the higher atmospheric pollution level.

EPIDEMIOLOGY OF LYMPHOMAS

B.R. Duvvuri, Guntur Medical College, Dept. of Pathology, *Guntur 522004, Andhra Pradesh, India* (D-IARC-79-272)

It has been observed that the incidence of malignant lymphomas is high in Guntur District and surrounding areas, compared to other districts of South India, and, further, that the incidence of these neoplasms has considerably increased in recent years. Data about the age and frequency, geographical distribution, occupation and economic status of the patients with lymphomas are being collected. These districts in Andhra Pradesh are mainly dependent on agriculture, and the population uses and handles large quantities of fertilizers, pesticides, etc. It is proposed to determine whether there is any relation between these exposures and the high incidence of lymphomas.

ANIMAL CONTACTS IN YOUNGER VICTIMS OF HODGKIN'S DISEASE

H. Doerken, Universitat Hamburg, Medizinische Facultat, First Medical Clinic, *Martinistrasse 52, 2000 Hamburg 20, Federal Republic of Germany* (D-IARC-76-207)

With the support of all 54 children's hospitals, 101 offices of the sanitary board, the cancer registry of Hamburg, etc., 140 children (2-14 years old) with Hodgkin's disease have been traced in Northern Germany (Schleswig-Holstein, Niedersachsen, Hamburg and Bremen) since the 1939-1945 war. All cases were histologically proven. Personal contact could be established with 133 families. Of the parents of these children, 33.1% had been engaged in agricultural occupations. In the retrospective studies contact with domestic animals was most impressive, especially that with rabbits (84.2%). Other animals, however, could not be overlooked e.g., pigs (45.95%). The difficulties in obtaining suitable controls - because of the widespread and changing keeping of animals - are considerable. The epidemiological results lead to the conclusion that Hodgkin's disease is a zoonosis. This work (Arch. Geschwulstforsch. 45: 283-298, 1975) continues with analysis of the 15-19 years age group, looking initially for clustering and contacts with domestic animals in a case-control study of some 50 cases.

ETIOLOGY AND PREVENTION OF ORAL LEUKOPLAKIAS AND THEIR MALIGNANT TRANSFORMATION

J.J. Pindborg, Kobenhavns Tandlaegehojskole, Dept. of Oral Pathology, *Universitetsparken 4, DK2100 Copenhagen OE, Denmark* (D-IARC-79-134)

Oral leukoplakia is well-known as a precancerous condition. On this assumption the aim of the present study has been to analyze prospectively the aetiology and pathogenesis of oral leukoplakias as well as the aetiology and pathogenesis of carcinomas developing in such leukoplakias. In this context availability of means of early diagnosis of oral carcinoma is important. By October 1978 the study comprised 750 persons who had all had a biopsy taken at the first examination. Follow-up biopsies have been performed in case of morphological changes of the lesions. Over the years the annual follow-up for each year has covered 95.6% of the persons with only small variations from one year to another.

EPIDEMIOLOGY OF CANCER IN CANADIAN HUTTERITES

K. Morgan, University of Alberta, Dept. of Genetics, *Edmonton, Alberta, Canada* T6G 2E1 (D-IARC-79-70)

Hutterites are members of a genetically isolated Christian sect who live in approximately 240 farming colonies in the Canadian Prairie Provinces and United States border states. In 1971 there were approximately 13,000 Hutterites living in the Prairie Provinces of Alberta, Saskatchewan, and Manitoba comprising over 70 percent of North American Hutterite colonies. Three major subdivisions of the Hutterites, the Dariusleut, Lehrerleut, and Schmiedeleut are distributed as follows: both Dariusleut ad Lehrerleut in Alberta and Saskatchewan, and only Schmiedeleut in Manitoba. Over 200 Hutterite cases of cancer were ascertained from the three population-based provincial registries by a search of surnames for the period 1951-76. Approximately half of these cases were diagnosed in Alberta and most of the remainder in Manitoba. Comparative analyses of cancer incidence will be undertaken with respect to geography and the three major endogamous subdivisions of the Hutterite population. Preliminary results for this data set corroborate the patterns of both high- and low-risk sites determined for Alberta Hutterites.

COLLABORATIVE EPIDEMIOLOGICAL STUDY ON THE FEASIBILITY OF PREVENTING COLONIC AND RECTAL CANCERS

F.M. Martin, Universite de Dijon, Faculte de Medecine, Dept. of Immunology, *7 Blvd. Jeanne d'Arc, Dijon, France* 21000 (D-IARC-79-167)

Colonic and rectal cancers represent a major cause of cancer mortality in France. They seem to result, in most cases, from transformation of precancerous lesions - intestinal polyps. The survey aims at evaluating the exact frequency of colonic and rectal polyps in gastroenterology clinic population, assessing the value of examinations used for their detection (double contrast enema, fiberoptic endoscopy, assessing the prevalence of polyps and cancers in the study population, determing the effect of routine excision of polyps on the incidence of colorectal cancers. For this, eight medical or surgical centers register patients or asymptomatic individuals, among whom routine screening of colorectal tumors are carried out. This study was activated on January 1977; by November 1978, 1,242 cases had been registered.

FEASIBILITY STUDY OF BREAST CANCER SCREENING

A.B. Miller, National Cancer Inst. of Canada, Epidemiology Unit, *77 Bloor St. W., Toronto, Ontario, Canada* M5S 2V7 (D-IARC-78-90)

A project is being initiated in Toronto with the collaboration of the College of Family Physicians of Canada and the Women's College Hospital of Toronto to evaluate the feasibility of the procedures planned for a national study of breast cancer screening in Canada. Approximately twelve family physicians will be invited to identify women aged 40 to 64 in their practice, from whom data on identifying information and risk factors for breast cancer will be collected by means of a self-administered questionnaire. These women will then be assessed by the physician for their stability for participation in the study in which approximately half the women would be chosen at random to (1) be invited to attend the Women's College Hospital for a breast cancer screening examination including mammography and clinical examination by a nurse, or (2) to remain under the care of the family physician without such referral. All women participating in this study will be taught breast self-examination. Informed consent to the transfer of the questionnaire to the National Cancer Institute of Canada, Epidemiology Unit, and to randomization will be obtained. In six month period approximately 1,000 women will be screened. Additional data on dietary and other variables will be obtained from those attending the screening center. It is anticipated that this will be the first stage of a study which will eventually be carried out across Canada and which will involve the recruitment and randomization of approximately 100,000 women aged 40 to 59.

DIET AND BOWEL CANCER

A.B. Miller, National Cancer Inst. of Canada, Epidemiology Unit, Dept. of Preventive Medicine & Biostatistics, *121 St. Joseph St., Toronto, Ontario, Canada* M5S 2R9 (D-IARC-79-106)

The study has been designed to investigate the role of diet in the causation of bowel cancer. A high intake of protein, fat and refined carbohydrates and a low intake of fibre have all been associated with high incidence of large bowel cancer. This is a case-control study to be conducted in two geographically distinct areas of Canada -Metropolitan Toronto and Calgary. In both areas an unselected series of newly diagnosed patients with bowel cancer will be admitted to the study. Data from such patients will be compared against age- and sex-matched neighbourhood and frequency-matched hospital controls.

CANCERS OF THE OESOPHAGUS AND RECTUM-ANUS - A CASE-CONTROL STUDY AT THE CITIES OF SAO PAULO AND RECIFE, BRAZIL

A.P. Mirra, Universidade de Sao Paulo, School of Public Health, Dept. of Epidemiology, *Avenida Dr. Arnaldo, 715-10 A, Sao Paulo, Sao Paulo, Brazil* (D-IARC-79-55)

The objectives of these investigations are: (1) to study the association between possible risk factors and cancer of the oesophagus and rectum-anus in a sample of patients from Sao Paulo and Recife (Brazil) and (2) to study in a sample of autopsies from residents of Sao Paulo frequency of precancerous lesions in the oesophagus and rectum, and to measure the association between these findings and

the same possible risk factors of the case-control study. For the case-control study both cases and controls will be selected from the files of the cancer registries of Sao Paulo and Recife. These patients will be of both sexes, 35-64 years old, with diagnosis confirmed histologically. For the precancerous lesions study the oesophagus and rectum will be cut in ten slices in four blocks and nine slices in three blocks respectively and slides will be examined by four different pathologists.

EXOGENOUS OESTROGENS AND THE DEVELOPMENT OF CANCER OF BREAST AND ENDOMETRIUM

R.W. Morgan, University of Toronto, Faculty of Medicine, Dept. of Preventive Medicine & Biostatistics, *92 College St., Toronto, Ontario, Canada* M5S 1A1 (D-IARC-79-107)

This retrospective cohort study is designed to examine the risk of breast cancer and endometrial cancer in menopausal and postmenopausal women who had received oestrogen therapy for other than contraceptive purposes. The study group is composed of 1,678 women (ages 40-55) in Toronto, who, between 1960 and 1970, were started on long-term oestrogen therapy for menopause (Cohort A). Drug use information and epidemiological data are being obtained from the following sources: gynecologists' records, Ontario Cancer Registry, Ontario Cancer Foundation, and telephone interviews. The incidence rates for breast cancer and endometrial cancer will be compared with age-specific incidence and mortality rates of the female population of Ontario (Cohort B). The mortality rates for the study population will also be compared with age-specific cancer mortality rates of the Canadian female population (Cohort C). An estimate will be made of the relative and attributable risk of developing malignant breast disease or endometrial carcinoma and of dose-response relationships of oestrogens to disease.

RELATIVE AND ATTRIBUTABLE CANCER RISKS BY SMOKING HISTORY

D.T. Wigle, Canadian Dept. of National Health & Welfare, Lab. Centre for Disease Control, *Tunneys Pasture, Ottawa, Ontario, Canada* K1A 0L2 (D-IARC-79-90)

The purpose of the study is to estimate the current relative and attributable risks by sex and cancer site for smokers in a relatively unpolluted environment. All persons who first attended one of the four cancer clinics in Alberta during the period 1971-1973 were interviewed prior to further clinical investigation. The questionnaire included several items on the history of residence, occupation and smoking. Relative and attributable risks for several cancer sites will be calculated using several comparison groups: persons with cancer sites with no known association with smoking; persons interviewed in the Canadian Labor Force Survey; and persons interviewed during the Nutrition Canada Survey.

RETINOBLASTOMA IN FINLAND SINCE 1912 - INCIDENCE OF OTHER MALIGNANT NEOPLASMS IN RETINOBLASTOMA PATIENTS AND THEIR RELATIVES

A. Tarkkanen, Helsingin Yliopisto, *Fabianinkatu 33, SF00290 Helsinki, Finland* (D-IARC-79-154)

It has been suggested that retinoblastoma might be used as an index cancer to which the frequency of other cancers could be compared. Hence efforts should be made to bring to light data on this cancer from different countries of the world. It has also been shown that bilateral retinoblastoma survivors may be more likely to develop another primary malignant neoplasm than any other cancer patients. It is proposed to estimate the incidence of other malignant neoplasms in retinoblastoma patients and their relatives. The data will be collected from Finland with the pathology laboratory of the Helsinki University Eye Hospital as the main source of information.

RELATION OF ATROPHIC GASTRITIS AND OPERATED STOMACH TO GASTRIC CARCINOMA

M. Siurala, (No Performing Organization Reported), *Finland* (D-IARC-78-135)

OBJECTIVES: (1) Long-term follow-up of atrophic gastritis (AG). One hundred and sixteen with AG of the body mucosa and 261 control subjects with normal mucosa or superficial gastritis have been followed up for 23-27 years. Ten gastric carcinomas and four adenomas were found in the AG group. By 1977 one case of carcinoma had been found in controls. (2) Morphology, function and immunology in gastric carcinoma families. Three hundred and eleven first-degree relatives of 73 probands with gastric carcinoma and 358 first-degree relatives of 73 control probands computer matched from a general population were studied by direct vision gastric biopsy, and by functional and immunological methods. Preliminary results suggest that AG, intestinal metaplasia, mucosal atypia and achlorhydria occur in cancer families more often and at a younger age than in the general population.

EPIDEMIOLOGY OF MALIGNANT TUMORS IN CHILDHOOD - PROGNOSIS OF WILMS' TUMOUR

Z. Erdoes, Semmelweis Orvostudomanyi Egyetem, Dept. of Paediatrics, *Ulloi Utca 26, Budapest, Hungary* (D-IARC-79-244)

The frequency of malignant neoplasms, especially Wilms' tumour, has been followed since 1947 in the 1st Dept. of Paediatrics of the Semmelweis Medical School, Budapest. No increase in the number of malignant tumours was found, a finding consistent with data from other countries. In this period, considerable improvement in the prognosis of Wilms' tumour, recovery in 50-70 percent of the cases has been noted; one patient with cured Wilms' tumour has been followed up for 36 years. Observations continue. Over the next 2 years it is intended to record the exact geographical sites where children with cancer are found. In odults it has been found that the highest frequency in Hungary occurs in the regions bordering on Austria. In the Transdanubian region in Hungary the number of cancer cases on the southern shore of the Lake Balaton is higher than in other parts of the country; the highest frequency of Down's Syndrome was also noted in this region.

CANCER INCIDENCE IN THE DISTRICT OF CLUJ, ROMANIA

G. Bolba, Oncological Inst. of Cluj-Napoca, Epidemiology & Statistics, *Republicii Nr. 34-36, R3400 Cluj-Napoca, Romania* (D-IARC-78-417)

This cancer registry covers the district of Cluj, Romania and is located in the Oncological Institute of Cluj-Napoca. The population of the district, at the census taken on 1st July 1972, was 334,789 males and 342,820 females. Crude mortality from cancer, both sexes, in 1971 was 136.1 per 100,000. Preliminary results from the cancer registry in 1974-1975 show a crude incidence of 181.1 per 100,000 in males and 153.1 per 100,000 in females. (1,216 and 1,052 new cases respectively). The cancer registry has to become an integral part of the cancer prevention and medical care activities.

ATLAS OF CANCER MORTALITY BY CITIES, TOWNS AND VILLAGES IN JAPAN

S. Anzai, Ministry of Health & Welfare, Dept. of Statistics & Information, *42 Honmura Chiyo, Ichigaya, Shinjuku-ku, Tokyo, Tokyo, Japan* (D-IARC-79-387)

Mapping of age-adjusted cancer mortality by cities, towns and villages from 1969 to 1975 for comparison with other maps giving distribution of various environmental factors. Although difficulties have arisen in calculating the rates for small areas because of rapid change of population size and amalgamation of administrative districts, most of the problems have already been solved. The maps have partly been completed. Work continues.

GEOGRAPHICAL DISTRIBUTION, SOCIOLOGY AND CLINICAL AND MICROSCOPICAL PICTURE OF CERVIX UTERI CARCINOMA IN STEIERMARK

H. Pickel, Universitat Frauenklinik, Zytologisch Histologisches Lab, *Auenbruggerplatz 14, 8036 Graz, Austria* (D-IARC-79-37)

Correlation will be sought for patients with cervix uteri carcinoma residing in the Federal Land of Steiermark between place of residence, social status and clinical stage of the tumor. Relations between the above and the frequency and localization of lymph node metastases, histological appearance and frequency of recurrence will be examined.

SUPPORTED BY (No Supporting Organization Reported) funds n.a.

ECOLOGICAL ANALYSIS OF CANCER MORTALITY IN LOWER SAXONY

M. Pflanz, Medizinische Hochschule Hannover, Institut fuer Epidemiologie und Sozialmedizin, *Karl Wiechert Allee 9, D3000 Hannover 61, Federal Republic of Germany* (D-IARC-79-209)

The study aims to detect relationships between cancer mortality (1968 and 1971) and socioeconomic or environmental factors by multivariate analysis. The sex-specific age-standardized data will be correlated with about 70 socioeconomic variables. Spatial relationship between chemical plants, lead smelters and other environmental hazards on one hand, and counties with high cancer mortality for specific sites on the other hand, will be examined. The study method is similar to that used in the analysis of cancer mortality in the United States counties.

MALIGNANT DISEASES IN GREENLAND

N.H. Nielsen, Kobenhavns Universitet, Inst. of Forensic Medicine, Dept. of Forensic Pathology, *Frederik den Femtes Vej 11, DK2100 Copenhagen OE, Denmark* (D-IARC-79-133)

This is an epidemiological study of total cancer incidence in Greenland as well as incidence of all specific types of malingancy. Records of all malignant cases diagnosed in this century are reviewed for medical and demographic information. The aim of the project is primarily to evaluate possible spatial or geographical gradients of frequency and to identify possible risk factors or risk groups.

2.2391,

EPSTEIN-BARR VIRUS (EBV) IN HUMAN DISEASE - A SERO-EPIDEMIOLOGICAL STUDY

J.A. Didier, Universite Paul Sabatier, Faculte de Medecine, Bacteriologie & Virologie Lab, *C.H.U. Rangueil, 31400 Toulouse Cedex, France* (D-IARC-78-180)

EBV antibodies are sought in various groups of normal subjects and patients including infectious mononucleosis syndromes, various acute or chronic diseases, malignant disease and persons with a transplanted organ. The study of the different types of antibodies produced, in response to EBV-induced antigens, in the host cell enables definition of the profile of EBV antibodies in these subjects. By comparing the different serological profiles and studying their development over time and in relation to whether there are clinical signs, it is possible to assess the host-virus relationship and the role of the EBV infections in human desease.

2.2397,

EPIDEMIOLOGY OF THYROID NODULES

H. Lucot, Centre Claudius Regaud, Services de Medecine Nucleaire de Chirurgie et de Medecine, *11 Rue Piquemil, 31052 Toulouse, France* (D-IARC-79-194)

Mortality from thyroid cancer seems more common in Midi-Pyrenees than in other regions of France. Over a period of 20 years the Claudius Regaud Center has collected a very large number of patients with thyroid nodules, many of which have been microscopically confirmed. The purpose of the study is to correlate habitat with: (1) benign and malignant thyroid tumors: (2) different types of malignant tumors. The Midi-Pyrenees region is demographically rather simple. In the North, in the Massif Central range, there is an epidemiological cluster of goiters (Aveyron-Tarn) and in the South, in the Hautes-Pyrenees-Ariege range, there is another. Some of our patients come from the Aude department, between the Montagne-Noire and the Pyrenees. There are also Italian migrants (mainly from Treviso, Udine, Venice) and Spanish migrants (mainly from Aragon and Catalonia) as well as white migrants from North Africa, numerous before 1962, and Poles who migrated into mining regions around 1931. Each patient with benign and malignant thyroid nodules has been questioned about residential history, diet, familial history of thyroid disease and personal habits. The distribution of thyroid disease will be compared with that of population distribution, distinguishing between those with change of residence from the others. There is a clear excess of females (83 percent of benign and 75 percent of malignant neoplasms). Follicular cancers seem to be more frequent than papillary, particularly where benign lesions are common.

2.2400,

CANCER RISK IN VEGETARIANS

R.R. Frentzel Beyme, Deutsches Krebsforschungszentrum, Institut fuer Dokumentation Information und Statistik, *Im Neuenheimer Feld 280, 6900 Heidelberg, Federal Republic of Germany* (D-IARC-79-211)

Animal experiments have shown many nitrosamines to be carcinogenic. Nitrosamine precursors in human food and vegetables have been investigated and high concentrations in certain vegetables suggest the possibility of a higher risk of cancer in persons consuming particular types of greens. Analytical studies together with a morbidity and mortality survey of a cohort of vegetarians are being undertaken to investigate a postulated relationship between cancer incidence and dietary habits. Control groups will be comprised of persons who have also willingly chosen a so-called 'reformed' life style (i.e., preference of a natural diet, but not exclusively vegetarian) as well as industrial employee populations considered to live on a conventional diet and being otherwise comparable (education, age, sociological background).

OESOPHAGUS CARCINOMA AND THE HABITS OF SMOKING, ALCOHOL DRINKING AND 'CHIMARRAO'

J.K. Almeida, Universidade Federal do Rio Grande do Sul, School of Medicine, Dept. of Surgery, *Rua Goitacaz 129, Vila Assuncao Paulo Gama, Porto Alegre 90000, Brazil* (D-IARC-79-52)

Oesophagus carcinoma is frequent in the state of Rio Grande do Sul. A characteristic of the rural population of this state is the drinking of 'gaucho' tea (Chimarrao, mate), a very hot beverage. This tea is consumed daily in large quantities from an early age. Other habits such as smoking and consumption of alcohol also exist. The main objective of the present study is to investigate the degree of association between the habits of smoking, alcohol drinking and 'Chimarrao' and oesophagus carcinoma. The study is prospective in nature.

EPIDEMIOLOGY AND CLUSTERS OF TUMORS IN CHILDHOOD, FREQUENCY AND GEOGRAPHICAL DISTRIBUTION

O. Bilek, Inst. of Pediatric Research, *Cernopolni 9, Brno 66262, Czechoslovakia* (D-IARC-79-123)

OBJECTIVES: In 1960-1968, 104 cases of childhood leukemia were observed in South Moravia. A significant clustering in space (0-12 km distance) and time (0-1, 0-2 years) was found (Blut, 21, 180-185, 1970). We intend to continue this study as these population groups, which could be regarded as genetic isolates, are very suitable for comparative studies of genetic factors. The main object of the study will be: (1) To register all cases of childhood leukemia from 1969 onwards; (2) to compare the previous (1960-1968) and the new (1969-1980) results; (3) to study the families with malignancy genealogically and (4) to study the influence of environmental factors on the incidence of leukemia, if any.

STUDIES AIMED TOWARDS FACILITATING LESS HARMFUL SMOKING HABITS

W.F. Forbes, University of Waterloo, Faculty of Mathematics, *University Ave. W., Waterloo, Ontario, Canada* N2L 3G1 (D-IARC-78-100)

Cigarette smoking is known to represent one of the main risk factors for lung cancer, and is also important in the aetiology of a number of other diseases. The objectives of the present study include: (1) the study of regional variations of various smoking-related and other diseases; (2) the undertaking of various surveys and the analyses of survey data, both at school age and in adult populations to estimate the prevalence of smoking habits in Canadian populations; (3) the study of individual smokers to determine their ability to adjust to a less hazardous cigarette (i.e., one delivering less tar, nicotine and carbon monoxide); (4) the analysis of cigarette consumption and sales data to estimate the effect of price on consumption, and to study the relationship between advertising, sales, and tar content for Canadian cigarettes; and (6) the collection of autopsy material from smokers and non-smokers, in order to investigate differences in trace-metal levels between smokers and non-smokers (particularly for cadmium and lead), and to evaluate the importance of cadmium and lead in human disease processes.

CANCER MORTALITY IN SWITZERLAND BY SITE, 1969 - 1972

R.F. Gass, University of Bern, Dept. of Social & Preventive Medicine, *Waldheimstrasse 18, 3012 Bern, Switzerland*

The purpose of this project is to identify variables associated with high or low mortality from cancer of different sites, based on the age-adjusted rates in the 25 cantons and 183 districts of Switzerland. The analysis is based on all deaths having occurred in Switzerland from 1969 through 1972, and on the population figures from the census of December 1970. A computer program has been prepared, testing for homogeneity, linearity, normality and mortality ratios, and for their statistical significance. Demographic, socioeconomic and environmental factors are examined by multiple regression analysis. Cancers of the stomach, oesophagus and breast are of primary interest. The results permit formulation and specification of hypotheses which will require further testing.

CASE-CONTROL STUDY OF ETIOLOGICAL FACTORS IN ORAL, PHARYNGEAL, LARYNGEAL AND SOME OTHER FORMS OF CANCER AND ORAL PRECANCEROUS LESIONS

P. Gangadharan, Tata Memorial Hospital, Medical Records & Statistics, *Dr. Ernest Borges Marg, Parel, Bombay 400012, Maharashtra, India* (D-IARC-78-246)

Almost 50% of all cancer cases seen in the Tata Memorial Hospital were in the regions of oral cavity, pharynx and larynx. Earlier studies have shown that chewing and smoking were statistically associated with the occurrence of cancer in these anatomical locations. The aim of the present investigation is to study the role of these factors in detail with regard to social groups (religious communities), anatomical locations of cancer, histologic types, dose-effect relationship, effect of other factors like oral hygiene, alcohol, etc. Patients attending the outpatient departments of the Tata Memorial Hospital are interviewed (using a special pro forma) with regard to their smoking and chewing habits. Other pertinent information is also collected from them. Since 1963 we have thus interviewed more than 10,000 cancer patients. This data is under analysis and will be compared with data obtained from the non-cancer patients attending the Tata Memorial Hospital. Differences between cases and controls will be subjected to detailed analysis in this retrospective study.

STUDY OF RISK FACTORS IN CERVICAL CANCER

M.R. Galesanu, Inst. de Medicina si Farmacie, School of Medicine, Radiological Clinic, *Strada Universitatii 16, c/o Radiological Hospital, Iasi, Romania* (D-IARC-79-474)

The purpose of the study is to establish possible correlations between the incidence of cervical cancer and some individual factors such as age at puberty, age at marriage, number of births and number of abortions. Such factors are found in rural areas where puberty and marriage occur at an early age, with numerous children. The studied population is taken from inpatients treated at the X-ray Clinic, Medical and Pharmaceutical Institute, Iasi, Romania. As about 400 new patients are admitted each year, we hope to study at least 2,000 cases within five years.

LEUKEMIA IN NAGPUR, INDIA

S.V. Grover, Government Medical College, Dept. of Pathology, *Ajni, Nagpur, India* (D-IARC-79-276)

The objective of this study is to assess the prevalence of leukemia and lympho-reticular malignancies in Nagpur. In a total of 242 patients with lymphoproliferative disorders the prevalence of acute lymphatic leukemia and chronic lymphatic leukemia was 26.03%, Hodgkin's disease 33.06%, non-Hodgkin's lymphoma 33.47%, multiple mononucliosis, mycosis fungoides, Waldenstroem's macroglobulinemia and unclassified 2.89%. The maximum number of chronic infections occurred in patients with Hodgkin's disease in the form of tuberculosis, leprosy and fungal infections (especially lymphocytic depleted type). In Hodgkin's lymphoma and non-Hodgkin's lymphoma the serum IgC and IgA were significantly increased. IgM was significantly lowered in Hodgkin's lymphoma, but not in non-Hodgkin's lymphoma. Patients with Hodgkin's disease and associated infections had raised serum IgC and IgA but lowered IgM. These patients were Mantoux negative, hence it is presumed that the cell mediated immunity was impaired while the humoral immunity was maintained. Assessment of cellular immunity status is still being worked out.

SELECTION AND FOLLOW-UP OF HIGH-RISK GROUPS FOR BREAST CANCER IN THE ESTONIAN S.S.R.

E. Hint, Ministry of Health of the Estonian SSR, Inst. Eksper. i Klin. Medit., Dept. of Clinical Oncology, *42 Hiiu St., Talliinn 200015, Estonian S S R, Union of Soviet Soc. Republics* (D-IARC-79-1084)

Epidemiological information concerning risk factors for breast cancer has been obtained from 15,000 women using a special punch card. Two main groups are being followed. The first group (7,500) has been screened by clinical examination of the breast. If disease was suspected, and confirmed, conservative or surgical treatment was given and this entire group will in future undergo regular breast examination, lesions being treated as they are found. The second group (7,599) consists of women for whom only the epidemiological information has been collected. These women will be offered treatment on request as for the general population. On the basis of data from the Cancer Registry, the incidence of breast cancer in general population and in both of the above groups will be compared. The significance of various risk factors and genetic variables in particular, and the effect of this screening program will be evaluated.

STUDY OF ISONIAZID, TUBERCULOSIS AND CANCER

A.B. Miller, National Cancer Inst. of Canada, Epidemiology Unit, Dept. of Preventive Medicine & Biostatistics, *121 St. Joseph St., Toronto, Ontario, Canada* M5S 2R9 (D-IARC-79-102)

Isoniazid (INH) has been used extensively for both the prophylaxis and treatment of tuberculosis since

its widespread introduction in 1952. It has been reported, however, that INH is carcinogenic in rodents and it is therefore important to examine its possible carcinogenic effects in man using a large human population. The present study is of a cohort of tuberculosis patients first admitted to Canadian sanatoria between the years 1952 and 1960. Records for all such admissions were maintained on the National Tuberculosis Register and these have been coded and key punched. The records contain identifying information together with information on the treatment used including a record of whether or not INH was given. These records have been linked using computerized record linkage techniques in order to bring together records pertaining to the same individual. Such records have been combined into composite records and these records in turn have been linked to the mortality data base maintained by Statistics Canada for the years 1952-1973 in order to ascertain the mortality experience of the cohort. In addition, a further linkage has been carried out to the cancer incidence data file maintained by Statistics Canada for the years 1969-1973. Analyses are currently being conducted to examine the mortality and cancer incidence experience of the cohort with respect to their exposure or non-exposure to INH. The study population consists of approximately 76,000 individuals and the numbers should be adequate to reveal any significant excess of cancer of the major target organs occurring in the group exposed to INH.

THE SWEDISH TWIN REGISTRY STUDIES

L.T. Friberg, Karolinska Institutet, Dept. of Environmental Hygiene, *Solnavagen 1, S10401 Stockholm 60, Sweden* (D-IARC-79-516)

In 1961 the Twin Registry covered about 10,000 same-sexed pairs born 1886-1925. The registry was expanded in 1973 to include also about 15,000 paris born 1926-1958. The aim of the twin registry is to study influences of the environment on morbidity and mortality. Morbidity data can be obtained from the Swedish Cancer Registry. The mortality data are evaluated through a continuous follow-up of mortality within the registries. Progress to date was reported in Acta Medica Scandinavia, Suppl. 612, 1977, in 'The Interactions of Smoking, Environment and Heredity and Their Implications for Disease Etiology'.

IMMUNOGENETIC AND IMMUNOLOGICAL ASPECTS OF NASOPHARYNGEAL CARCINOMA (NPC)

S.H. Chan, University of Singapore, School of Medicine, Dept. of Microbiology, *Sepoy Lines, Singapore 3, Singapore*

HL-A profiles associated with risk of development of NPC and with prognosis have now been established. The haplotype A2 BW46 (Sin 2) is associated with a relative risk (RR) of 1.97 and 2.29 in two studies of newly diagnosed NPC patients. Another haplotype, AW19 B17, is associated with a RR of 2.80 and 2.60 in the two studies. AW19 B17 and, to a lesser extent, A2 BW46 have been found to be associated with poor survival in a restrospective study. HL-A - DR locus antigen typing in NPC patients has begun. NPC patients showed a higher frequency of DR locus blank antigen than controls. A local DR antisera, AH21, showed higher reactivity among the patients than controls (RR equals 8.0). A prospective study of HL-A profiles and prognosis in NPC is in progress. A prospective study of HL-A, Epstein-Barr virus serology and development of NPC in a normal population has also been started.

CANCER INCIDENCE AND MORTALITY OF SAO PAULO COUNTY

A.P. Mirra, Universidade de Sao Paulo, School of Public Health, Dept. of Epidemiology, *Avenida Dr. Arnaldo, 715-10 A, Sao Paulo, Sao Paulo, Brazil* (D-IARC-79-56)

OBJECTIVE: To study the cancer incidence and mortality in Sao Paulo County (descriptive epidemiology). In the second step to study the analytic epidemiology. The data are collected in standard files by collectors from the following sources: hospitals, clinics, homes for the aged, service of drug control, pathology laboratories, autopsy services and death certificates. The data received, after codification, are transferred to punched cards and magnetic tapes. The classification of cancer cases is made by the first name of the patient, last name of the patient and number of registration. Our unit is the cancer case and not the cancer patient. Each neoplasm is registered individually. The notification of cancer is compulsory.

2.2426,

RADIATION EXPOSURE AND MORTALITY IN FLUORSPAR MINERS

D.T. Wigle, Canadian Dept. of National Health & Welfare, Lab. Centre for Disease Control, *Tunneys Pasture, Ottawa, Ontario, Canada* K1A 0L2 (D-IARC-79-86)

The objective of the study is to evaluate the risk of death due to lung cancer as a function of cumulative exposure to radon and radon daughters in the fluorspar mines of St. Lawrence, Newfoundland. The mortality and adaptation exposure experience of over 2,000 men employed between 1933 and 1977 will be reviewed. Fluorspar mining in St. Lawrence (population 2,078, 1956 census) began in 1933 and by the period 1952-60, lung cancer accounted for 21 of the 71 total deaths: only 0.73 lung cancer deaths were expected based on proportional mortality rates for the province (O/E equals 29). Investigation in 1959 revealed the presence in air of radon and radon daughters at levels up to 193 SWL (1 SWL equals 100 pc/l for radon and 1.3 x 10 to the 5th power MeV total potential alpha-energy per liter for daughters) in non-working, unventilated areas. The average exposure of miners was estimated to be 2.5-10 SWL. Improved ventilation and monitoring of individual exposure were started in 1960. Current studies are directed towards evaluation of control procedures and analysis of the associations between radiation exposure and mortality utilizing individual exposure data and man-years at risk.

TEESSIDE STUDY

G. Dean, Medico Social Research Board, *73 Lower Baggot St., Dublin 2, Ireland* (D-IARC-79-290)

The objectives of this study were to determine how, during a recent period, mortality from lung cancer, bronchitis, heart disease, and stroke related to air pollution, social class, smoking (with particular emphasis on whether the cigarette smoked was filter or plain) and other factors, and to examine changes in lung cancer and bronchitis mortality during the last ten years in relation to changes in air pollution levels and smoking habits. The surviving relatives of those people in Cleveland County who had died from lung cancer or bronchitis in 1969-72 (males) or 1969-1972 (females), heart attack in 1971-1972 (males only) or stroke in 1966-1972 (also males only) were interviewed. Details of number of factors, including, in particular, the decedent's probable exposure to air pollution and smoking habits, were obtained. Similar information for the living population was obtained for a random sample in 1973. It was thus possible to relate mortality to the factors measured and also to compare mortality rates from lung cancer and bronchitis with those of the similar study carried out in Teesside in 1963. The study is to be published in two parts by the Tobacco Research Council, London, as their Research Paper 14 'Report on a second retrospective mortality study in North-East England'. Part I 'Factors related to mortality from lung cancer, bronchitis, heart diseases and stroke in Cleveland County, with particular emphasis on the relative risks associated with smoking filter and plain cigarettes' appeared in September 1977. Part II 'Changes in lung cancer and bronchitis mortality and in other relevant factors occurring in areas of North-East England 1963-72' appeared in the 1978 TRC Research Papers, 14.

LONG-TERM CANCER MORTALITY TRENDS AMONG KRAKOW INHABITANTS IN RELATION TO DEMOGRAPHY AND ENVIRONMENT

W. Jedrychowski, Akademia Medyczna W Krakowie, Inst. of Social Medicine, Dept. of Epidemiology, *Ul. Kopernika 7, 31034 Cracow, Poland* (D-IARC-79-454)

The spatial analysis of mortality due to malignant neoplasms in the population of Cracow will cover the ten-year period 1974-1984. The city of Cracow has over half a million inhabitants and its four districts differ in regard to degree of air pollution, smoking habits, fertility and other social and environmental factors. The aim of the study is to make a comparison between data on mortality from malignant neoplasms in the four districts. Death certificates taken from the statistical office on a monthly basis have been used in the analysis of malignant neoplasms. Cancer mortality data are analyzed according to sex, place of residence and primary site. Age-specific and age-adjusted rates are computed for the total population and for each district. So far, data covering the years 1974-1978 have been collected and are currently being analyzed. The pilot study done for the year 1974 has shown that the most frequent causes of death in Cracow by sex were lung carcinoma in men and breast carcinoma in women. The highest age-adjusted rates were in the city center where the fertility rate was low and the level of atmospheric pollution, tobacco consumption and the proportion of working-class population appeared to be high.

THE CYTOLOGICAL DIAGNOSIS OF BLADDER TUMORS IN DYESTUFF WORKERS

S. Ishizu, Tokyo Womens Medical College, Dept. of Public Health, *10 Kawadacho Shinjuku-Ku, Tokyo 162, Tokyo, Japan*

The production and use of benzidine and beta-naphthylamine in the dye industry of Japan were prohibited by law in 1971. However, there are still 4,037 workmen (including retired men) who have been exposed to carcinogenic amines, and risk developing a bladder tumor in the future. This study aims to perform continuous follow-up urine examination of the workers. For the early detection of bladder tumors, routine cystoscopy was considered to be quite unsuitable. The Papanicolaou smear technique of urine examination was introduced into the dye industry of Japan in 1961. A total of 4,037 men were screened first by wet smear and then by Papanicolaou smear. During the 22 years from 1955 to 1977, 192 cases of occupational bladder tumor were discovered; 15 out of 108 men with positive Papanicolaou smears have shown no tumors on cystoscopy; 7 men with negative Papanicolaou smears showed bladder tumors on cystoscopy (false negative); 47 out of 137 men with suspicious Papanicolaou smears had bladder tumors. Seventeen specimens obtained from the occupational bladder tumor patients were histopathologically examined. Of these 17 specimens, 8 showed papillary cancer type, 6 showed an inverted proliferating tumor, and 3 were carcinoma in situ. This study continues.

2.2439,

MORTALITY OF BRITISH COKE-OVEN WORKERS

M. Jacobsen, Inst. of Occupational Medicine, Statistics Branch, *Roxburgh Pl., Edinburgh EH8 9SU, Scotland, United Kingdom* (D-IARC-79-588)

The objective of this investigation is to estimate death rates from cancers in general and lung cancer in particular among British coke-oven workers. A cohort of men employed in 1967 at industrial establishments involving coking operations is being studied. Men involved are or were employees of the British Steel Corporation or of a subsidiary of the National Coal Board. Analysis of a nine-year follow-up period suggests an occupationally related lung cancer hazard at some works, and that this hazard is considerably smaller than that reported among American coke workers. The study continues.

INSTITUTE OF PETROLEUM EPIDEMIOLOGICAL SURVEY

M.R. Alderson, Inst. of Cancer Research, Division of Epidemiology, *Clifton Ave., Sutton SM2 5PX, England, United Kingdom* (D-IARC-79-695)

The aim is to monitor background data in order to quantify the overall level of morbidity and mortality and examine the variation from disease in relation to broad categories of work or 'environment'. Some twenty companies in the oil industry have agreed to fund an epidemiological study through the Institute of Petroleum. Present plans are to collect data from eight refineries (three Shell, three BP, one Esso, and one Mobil); details are required about men who have been employed for at least a year from 1950 to 1975, including those who have left the industry, retired, or died. The analysis will examine mortality rates by cause (taking age, location, and type of work into account). Comparisons will be made between men doing different work within refineries, and with the mortality data for men in other industries in the same region as each refinery and in the country as a whole. Such a study can quantify the general mortality (and thus indirectly the overall level of health in the industry). Examination of material on individual diseases may identify specific issues that warrant detailed study. This study is now being extended to workers at various distribution centers for refinery products and maintenance staff at London Transport garages.

ANALYSIS OF URINES FOR NITROSAMINES FROM PATIENTS WITH BILHARZIASIS

R.M. Hicks, University of London, Middlesex Hospital Medical School, School of Pathology, *Riding House St., London W1P 7LD, England, United Kingdom* (D-IARC-79-624)

There is a high bladder cancer incidence in Egypt, in areas irrigated by canals from the Nile, and it is always linked with endemic bilharziasis. Bilharzial patients also frequently have chronic intractable bacterial infections of the urinary bladder. Many bacteria are capable of reducing nitrate to nitrite, and then nitrosating secondary and tertiary amines to nitrosamines. Secondary amines are normally in human urine. I have suggested, therefore, that nitrosamines could be a factor in the incidence of bladder cancer in Egypt, and if it is so, the bilharziasis is a co-factor, rather than a direct carcinogen. A pilot study has been undertaken with the collaboration of IARC, in which urines from bilharzia infested patients in Cairo and surrounding districts were analyzed by gas chromatography and mass spectrometry. Many of these patients had significantly higher levels of several nitrosamine species in their urines than did uninfested Egyptian and European individuals. For comparison, urines of European patients with chronic bacterial infections of the urinary tract were analyzed in the same way. This investigation will now be extended to other areas where bilharziasis is endemic.

GENETIC ASPECTS IN RELATION TO CANCER

V. Balakrishnan, Cancer Research Inst., Epidemiology Div., *Dr. Ernest Borges Marg, c/o Tata Memorial Ctr., Bombay 400012, Maharashtra, India* (D-IARC-79-260)

Indian society is divided into a large number of religious and linguistic communities, many of which are further subdivided into endogamous groups (castes and sub-castes). These groups not only differ in food habits, customs etc., but also restrict marriages within a group, leading to great differences in their gene pools. While some of these groups prohibit marriages between persons related up to three or four generations, some other groups have probably the highest levels of inbreeding in the world. Patients from all parts of India attend the Tata Memorial Hospital. Information collected from these patients is to be used to build up cancer profiles of the endogamous groups to see whether these differ in a manner not explained by their habits and customs. Information on close consanguinity is also collected to assess the effects of inbreeding. Patients diagnosed as not suffering from cancer will be used as controls. Information on about 2,500 cancer cases and 1,600 non-cancer cases collected during 1975-1976 was analysed. The cancer cases were distributed over about 30 sites, only sites in males and two sites in females having more than 100 cases. About 2,000 cases were interviewed in 1977. Collection of information is continuing.

CASE-CONTROL STUDY OF HIGH RISK FACTORS IN OVARIAN CARCINOMAS

J.J. Szamborski, Akademia Medyczna W Warszawie, Inst. of Obstetrics & Gynaecol, Dept. of Pathomorphology, *Karowa 2, 00315 Warsaw, Poland* (D-IARC-79-459)

The work published during the last years has shown some differences in prognosis and curability of ovarian carcinoma in relation to the histological type. The aim of this prospective study is to collect the clinical data concerning the biological status and previous gynecological history of patients with ovarian carcinoma and to explore the differences in these data between the patients with: serious carcinoma, mucinous carcinoma, endometrioid carcinoma and controls. Cancer-free patients attending the gynecological ward are used as controls. They are selected according to age to give a sample with approximately the same age structure as the ovarian carcinoma groups. The data is collected using a modified form of the ovarian tumour classification suggested by WHO. Subsequent analysis of possible risk factors will be undertaken.

STUDIES ON FAMILIAL GASTROINTESTINAL POLYPOSIS IN JAPAN

J. Utsunomiya, Tokyo Medical & Dental University, School of Medicine, Dept. of Surgery, *I-Chome, Yushima, Bunkyo-Ku, Tokyo 113, Tokyo, Japan* (D-IARC-79-397)

The objective of this study is to ascertain and register family members of patients with gastrointestinal polyposis in Japan in order to control this disease and to provide information for the genetic study on cancer. Information on the subjects was collected through inquiry, from literature, autopsy records and voluntary visits; pedigrees constructed by means of reviewing the official family register record (Koseki) and the presence of polyposes among relatives was ascertained by consulting the death certificate or by communicating with family members. Currently, 292 families suffering from familial polyposis coli (fpc) including Gardner Syndrome, 106 of Peutz-Jeghers Syndrome, 121 of multiple polyps and 50 of familial colon cancer with or without polyps are registered. A survey has been completed on 200 families of fpc and based on these materials, comprehensive studies are under way including clinicopathological studies of associated changes (gastric polyposis and occult osteomatous changes of fpc), genetical epidemiological analysis, cytogenetical study, genetic marker study and others.

A BREAST REGISTRY IN NORTHERN ALBERTA WITH RESEARCH AND CLINICAL APPLICATIONS

P.E. Burns, Dr. W.W. Cross Cancer Inst., Dept. of Radiation Oncology, *11560 University Ave., Edmonton, Alberta, Canada* T6G 1Z2 (D-IARC-79-61)

A breast registry was created in Northern Alberta to study the aetiology, epidemiology, diagnosis, treatment, and survival patterns of malignant and benign breast tumors. About 700 patients with benign conditions and 250 with newly diagnosed breast cancer attend the breast clinics at the Cross Institute each year. Interview data are collected from all patients, who represent 90% of all breast cancer registrations and about 30% of women treated for benign breast disease. More than half of all patients registered with breast cancer are assessed pre-operatively at these clinics by one of two clinicians. Data from the registry have been used to compare diagnostic accuracy, to study incidence trends, to assess the influence of exogenous hormones and other aetiologic factors, to compare 1968 and 1973 UICC staging and to determine factors related to survival of breast cancer patients.

DIFFERENTIAL MORTALITY PATTERNS BETWEEN NATIVE-BORN AUSTRALIANS AND MIGRANTS

M.G. McCall, University of Western Australia, School of Medicine, Dept. of Medicine, *Perth, W. Australia 6009, Australia* (D-IARC-79-23)

The initial data were published following the 1966 census. The cooperation of the Commonwealth Bureau of Statistics has been obtained to continue the study and data on all deaths in Australia (1962-1971) have been collated. 1971 was the last year of which census data are available and denominators for twenty-four migrant groups with seven periods of residence have been computed. Provision has been made for the inclusion of 1976 data when they

become available. The difficulty caused by the change to the ICD 8th Revision classification has been resolved and a numerator file for any given disease is available. From this, standardized mortality ratios for a wider range of malignancies and population groups can be computed and several publications are being prepared.

SMOKING AND CHEWING HABITS IN RELATION TO HEALTH - A PROSPECTIVE STUDY IN BOMBAY

K. Jayant, Cancer Research Inst., Epidemiology Div., *Dr. Ernest Borges Marg, c/o Tata Memorial Ctr., Bombay 400012, Maharashtra, India* (D-IARC-79-261)

A number of retrospective studies carried out in this country have demonstrated the association of smoking and chewing habits with oral and pharyngeal cancers. Laboratory and experimental studies on bidi smoke and betel quids have also served to establish this cause-effect relationship. To see whether the results obtained in retrospective studies are sustained in prospective studies in which large populations with known habits are followed for several years for the occurrence of cancer, a limited study of this nature has been in progress, following earlier pilot studies. About 7,000 white-collar workers and 3,500 blue-collar workers over the age of 35 have been followed up for varying periods since 1969. A preliminary analysis of the data on white collar workers is being undertaken.

CONTINUING RETROSPECTIVE STUDY OF ALL CASES OF MESOTHELIOMA IN NORTHERN IRELAND TO DETERMINE THEIR SOURCE OF ASBESTOS EXPOSURE

J.H. Langlands, Belfast City Hospital, Respiratory Investigation Center, *93 Lisburn Rd., Belfast BT9 7AB, United Kingdom* (D-IARC-79-566)

The objective of this study is to detect sources of asbestos exposure in the community which are sufficient to cause mesothelioma, in order to determine whether preventive measures applied to recognized sources of exposure are sufficient. Arrangements are made for all cases of mesothelioma to be reported to the investigators as soon as possible so as to obtain pathological material for examination after death.

TIME TRENDS IN AGE-SPECIFIC BREAST CANCER MORTALITY IN RELATION TO CHANGING DIETARY IODINE LEVELS

A.J. McMichael, Commonwealth Scientific & Industrial Research Org., Div. of Human Nutrition, *Kintore Ave., Adelaide, S. Australia 5000, Australia* (D-IARC-79-6)

From epidemiological and experimental research elsewhere, it has been postulated that dietary iodine deficiency increases the risk of female breast cancer. Increased oestrogenic stimulation of breast tissue, following increased activity of the hypothalamic-pituitary axis, has been suggested. In both Australia and the U.S.A. regions of iodine deficiency have been well documented (especially Tasmania and the Ohio-Kentucky region). Dietary iodine supplementation programs during the past 30-50 years may be reflected in a reduced risk of premenopausal breast cancer (i.e., the 'hormone-dependent' category) in recent years, particularly in women who have been iodine-sufficient since childhood. Mortality data for Australia and the U.S.A. are being analyzed for evidence of such trends in erstwhile iodine-deficient regions. Preliminary data for Tasmania (Australia) supports the hypothesis.

HODGKIN'S DISEASE IN WESTERN AUSTRALIA WITH SPECIAL REFERENCE TO CONTACT BETWEEN PATIENTS WITH THE DISEASE

M.L. Matthews, Cancer Council of Western Australia, Leukaemia & Allied Disorders Registry, *184 St. Georges Terr., Shenton Park, Perth, W. Australia 6000, Australia* (D-IARC-79-30)

Previous studies have suggested that Hodgkin's disease occurs more frequently in individuals who have had contact with patients with Hodgkin's disease than in those who have not. These studies have been designed to test this hypothesis. Patients with Hodgkin's disease have been notified to the Leukemia and Allied Disorders Registry in Western Australia since 1959. Data on these patients are being used to study space - time clustering of Hodgkin's disease and the coincident occurrence of this disease in pupils and teachers at schools in Western Australia. 108 patients with Hodgkin's disease registered since 1964 and surviving to June 1976 have been matched by sex, age and area of residence with members of the general population of Western Australia. Patients and controls have been interviewed to uncover evidence of contact. Data on relatives and close associates of Hodgkin's disease patients have been collected also to determine whether any of them have developed a lymphoproliferative or myeloproliferative disorder. Data are now being analyzed.

TOBACCO CONSUMPTION AMONG BELGIAN MILITARY RECRUITS

M. Graffar, Universite Libre de Bruxelles, Dept. of Epidemiology & Social Medicine, *50 Ave. Franklin Roosevelt, Campus Plaine, 1050 Brussels, Belgium*

The prevalence of cigarette smoking has been studied in a representative sample of Belgian draftees in order to assess the importance of this major health hazard. Among 2,023 French-speaking young men screened in 1977 cigarette smokers amounted to 60.7%, with a significant higher rate (63%) in young subjects compared to those 21 years old and more (55%). The prevalence is negatively correlated with degree of education: 65% for those with a primary or low technical degree, 56% for those with a secondary or middle technical degree and only 47% in those with university or higher technical education. In order to assess the effect of an anti-smoking campaign at the primary and secondary school level, organized by the Belgian Red Cross, another screening of draftees is planned in 1979.

EPIDEMIOLOGY OF LEUKEMIA AND ALLIED DISORDERS IN WESTERN AUSTRALIA

L.E. Dougan, Cancer Council of Western Australia, *184 St. Georges Terr., Shenton Park, Perth, W. Australia 6000, Australia* (D-IARC-79-27)

Patients have been notified to the Leukemia and Allied Disorders Registry in Western Australia since 1959. Further registrations were made by search of hospital morbidity indices, pathology and hematology department records and death certificate scrutiny. For patients prevalent in the period 1960 to 1969 the diagnoses were confirmed or otherwise by a diagnostic group of pathologists and hematologists after review of clinical and pathological material. Epidemiological and clinical data have been collected for those patients with confirmed diagnoses and incidence and mortality rates have been calculated by sex, age and geographical area. Other data collected includes irradiation exposure, drug ingestion, past medical history, family history, occupation, domicile, birth order, family size, parental ages, presence of other malignancy or congenital malformations, autopsy findings and death certification. Follow-up study is continuing in order to complete survival figures and data on the development of other malignancies. Since 1969 the registration of patients has continued but diagnoses are accepted without confirmation by the diagnostic group and less detailed epidemiological information is recorded. Copies of tabulations from the 1960-1969 survey are available on request.

GYNECOLOGICAL CANCER IN WESTERN AUSTRALIA WITH SPECIAL REFERENCE TO ROLE OF EXOGENOUS AND ENDOGENOUS OESTROGENS IN ENDOMETRIAL CANCER

B.K. Armstrong, Western Australian Public Health Dept., *60 Beaufort St., Perth, W. Australia 6000, Australia* (D-IARC-79-24)

The study will describe trends in mortality from gynecological cancer in Western Australia between 1930 and 1974 and incidence data collected by cancer registration between 1971 and 1974. The latter data will permit study by area of residence, occupation, race and country of birth. A retrospective case-control study of the role of oestrogen therapy with mainly ethinyl oestradiol in the aetiology of endometrial cancer is being undertaken and will include about 200 cases and 200 controls. Data on oestrogen receptors, and plasma and urinary oestrogen have been collected already on over 50 patients with endometrial cancer. Data will be collected also for appropriately matched controls and related to physical characteristics, obesity, diet and other factors.

INCIDENCE OF CHRONIC DISEASE AND UTILIZATION OF HEALTH SERVICES BY MIGRANTS TO WESTERN AUSTRALIA

B.K. Armstrong, Western Australian Public Health Dept., *60 Beaufort St., Perth, W. Australia 6000, Australia* (D-IARC-79-25)

The statutory collection of demographic and medical information on patients discharged from all hospitals in Western Australia renders possible the study of the incidence of chronic diseases which normally require hospitalization. Preliminary analyses have shown excesses of hospital admissions for gall bladder disease, acute pancreatitis, inflammatory bowel disease, lung cancer and chronic renal disease. These and other conditions are being studied in detail to ascertain whether true differences in incidence exist among migrants or whether the excesses observed are due to differential utilization of health services.

NATIONAL SURVEY OF CHILDHOOD CANCERS

K. Wilson, Marie Curie Memorial Foundation, Epidemiology Unit, *The Chart, Oxted RH8 0TL, England, United Kingdom*

This long-standing retrospective survey was orginally started in Oxford by Dr. A. Stewart in 1953 to study the aetiology of childhood cancers. It consists of interviews with the parents of children under 16 dying of cancer or leukemia in the United Kingdom and with parents of control children matched for age, sex and district; antenatal information is confirmed by application to clinics and doctors, and the case child's medical history is followed up through general practitioner and hospital notes. Surviving children have similarly been interviewed and followed up since 1962 by means of the regional cancer registries. In the past extensive studies have been made of the relation of obstetric low-level radiation to the increased risk of the child later developing neoplasia. The effect of viral diseases during pregnancy has also been found to increase the risk, but less convincingly. Present projects include: 1. A study of the effects of the use of ultrasound and of drug therapy during pregnancy, and of the possible relationship of these agents in the aetiology of childhood cancers. 2. A study of congenital defects found in children who later develop cancer or leukemia, and congenital defects in their siblings, together with a similar study of defects in matched control children and their siblings. 3. A study of all cases of Wilms' tumor, surviving and dead, whose diagnosis and initial treatment occurred in 1969-1973 to assess the difference in prognosis between those who were included in the M.R.C. Trial and those outside. This study is being done in collaboration with the C.C.R.G. in Oxford. 4. A study of 95 second primary tumors occurring in children after cure of their initial cancer is being undertaken with special attention to the effect of radiation and genetics.

EPIDEMIOLOGICAL STUDY ON WORKERS EXPOSED TO CHLOROMETHYL-METHYL ETHER (CMME) AND BIS-CHLOROMETHYL ETHER (BCME)

B. Terracini, Universita degli Studi di Torino, Istituto di Anatomia e Istologia Patologica, Dept. of Pathology, *Via Santena 7, I10126 Turin, Italy* (D-IARC-79-337)

In the Montedison plant in Castellanza (Varese, Italy) CMME was used in the manufacture of ion-exchange resins during 1946-63 and it has been used in the laboratory since that time. In addition, in several areas of the plant the concurrent presence of formaldehyde and HCL (precursors of BCME) has been observed. The number of workers employed since 1946 in the plant is about 2,500. Deaths are being traced through the records of the town of birth of each worker. Mortality rates will be related to the length and sector of work in the plant and compared to those of the general population in the province of Varese.

RETROSPECTIVE STUDY OF LEUKAEMIAS, LYMPHOMAS AND OTHER HEMATOLOGICAL NEOPLASMS

E. Quiroga Micheo, Grupo Argentino Cooperativo de Estudios Epid. en Hematologia, *Las Heras 1895, 1127 Buenos Aires, Argentina* (D-IARC-79-3)

Differences in mortality rates for these neoplasms have been observed among the different immigrant groups in Argentina. In addition, it was observed that where the water had a high content of arsenic, the mortality for lymphomas was greater than elsewhere. This case control study was planned to test this hypothesis. The controls were patients seen at the same hospital with diseases other than cancer and of the same sex and age group. Other factors which are believed to be related to these diseases are being investigated: familial occurrence, residence, prenatal factors, exposure to toxic agents, animals, radiation, and previous history of different diseases.

2.2483,

THE EFFECT OF EXOGENOUS OESTRIOL AND ANTIOESTROGENS ON BREAST CANCER INCIDENCE

M.A. Basombrio, Academia Nacional de Medicina, Inst. de Investigaciones Haematologicas, Seccion Leucemia Experimental, *Pacheco de Melo 3081, 1425 Buenos Aires, Argentina* (D-IARC-79-2)

Previous work has shown that full-term pregnancy before 25 years of age significantly reduces the incidence of breast cancer in women. The possible mechanism underlying this observation may be that the high production of oestriol which occurs during pregnancy could block cell receptors for the more 'carcinogenic' oestrogens, oestrone and oestradiol. The observation that oestriol prevents chemically induced mammary cancer in rats (Lemon, H.M.; Cancer Res. 35: 1341, 1975) poses the question of whether exogenous oestriol given early in life may prevent mammary cancer in women. A registry of women who are at high risk of developing first or second breast cancer, consisting of first order relatives of breast cancer patients and patients with unilateral breast tumor who have been 'cured' surgically, is being set up. Using this high-risk population, it is anticipated that the time normally required for a prospective study on the occurrence of the disease as a consequence of environmental factors will be more than halved. Particular attention is paid to the effect that administration of oestriol and/or antioestrogens may exert upon breast cancer incidence. The study is being organized as an inter-hospital registry which will record data on high-risk factors, parity and oestrogen treatments.

STUDY ON THE RELATIONSHIP BETWEEN CERVICAL CANCER AND HERPES SIMPLEX VIRUS TYPE 2

V. Vonka, Inst. of Sera & Vaccines, Experimental Virology, *W. Pieck 108, Prague 10, 10103, Czechoslovakia* (D-IARC-78-118)

Herpes simplex type 2 virus is suspected to be aetiologically related to squamous carcinoma of the cervix. This suspicion is mainly based on the epidemiological similarity of the venereal spread of the virus and the occurrence of cervical cancer, and on the excess occurrence of neutralizing antibodies to the virus among women with cervical neoplasia when compared with control women. A prospective study of 12-15,000 women between the ages of 25 and 40 is undertaken to find answers to the following two questions: 1) Does herpesvirus infection precede the cervical neoplastic changes? 2) Are the virus infection and the cancer covariables of sexual promiscuity? Pelvic examination will be performed on all women at enrollment and the examination will include cervical cytology and colposcopy. Severe dysplasia, carcinoma in situ and invasive cancer will be considered as evidence of neoplastic disease. Antibodies to herpes simplex type 2 virus will be assayed initially on a random sample of the study group and on all women who develop cervical neoplasia as well as in control subjects. Data regarding sexual and reproduction-associated attributes will be obtained. The women will be re-examined at intervals of 2 and years after enrollment. The observed disease will be used to estimate the risk with past herpes simplex

type 2 infections and with various aspects of the sexual and reproduction-associated attributes.

DIAGNOSTIC AND AETIOLOGICAL IMPLICATIONS OF MAMMOGRAPHIC CALCIFICATIONS IN BREAST DISEASE

D.V. Vakil, University of Toronto, Faculty of Medicine, Dept. of Preventive Medicine & Biostatistics, *92 College St., Toronto, Ontario, Canada* M5S 1A1 (D-IARC-79-109)

The presence of multiple punctate calcification in the breast and its association with breast carcinoma has been reported by many investigators. In the course of clinical mammography during the past several years we have detected calcifications in numerous cases of carcinoma of the breast and, in many of these, the presence of calcification on the mammogram in the absence of a palpable mass was the only sign of carcinoma. We have obtained genetic, epidemiological, pathological, and radiological information on 2,338 women who were radiographed for clinical indications of breast disease at the Toronto Western Hospital from 1968 to 1973. Biopsies or mastectomies were done for surgical or radiological suspicion of malignancy in these women. The biopsies indicated that 354 women had breast cancer, 1,713 had benign breast disease, and 272 had no apparent breast disease. We are studying the genetic, epidemiological, pathological, and radiological factors in those diagnosed as having breast cancer, those who had benign breast disease, and those without apparent breast disease. From the available pathological and radiological information on these women, we are also determining if a certain pattern of calcification correlates with (1) the presence of breast cancer, (2) the type of breast cancer, and (3) the type and degree of fibrocystic disease if carcinoma is not diagnosed pathologically.

THE POPULATION STUDY IN GLOSTRUP OF MEN AND WOMEN BORN IN 1914

M. Schroll, Kobenhavns Amts Sygehus Glostrup, Inst of Preventive Medicine, *2600 Glostrup, Denmark* (D-IARC-79-137)

The Glostrup population study of 60 year olds in 1974 was an epidemiological investigation of a cohort delimited by age and geographical conditions, which had been investigated previously in 1964. The investigation illustrates risk factors for arteriosclerotic cardiovascular disease in a Danish population, but many variables are registered at 50 and 60 years and interrelations found. In 1974, 15 men and 10 women of the originally investigated 514 men and 461 50 year old women had died from cancer. In 1974, all cancer diagnoses and treatment given during the ten years were registered. All participants were given a thorough clinical examination including X-rays of thorax and spine and all women had a vaginal smear taken. The cohort will be followed.

AN INVESTIGATION INTO ORAL CANCER AND ORAL PRECANCEROUS LESIONS IN INDIAN RURAL POPULATIONS IN RELATION TO TOBACCO HABITS

F.S. Mehta, Tata Inst. of Fundamental Research, Basic Dental Research Unit, *Homi Bhabha Rd., Bombay 400005, Maharashtra, India* (D-IARC-79-269)

Oral cancer is one of the most common forms of cancer in India. There is a strong belief that such cancer may be preceded by certain white lesions in the oral cavity, which are thus termed precancerous. It is known, mostly through hospital-based studies, that oral tobacco usage habits are associated with oral cancer and precancerous conditions. The main objectives of the present study are to (1) investigate the degree of association between tobacco usage habits, oral cancer and precancerous conditions and (2) elucidate the natural history of oral precancerous conditions from clinical and histological viewpoints. The study design is prospective in nature. In a first survey in 1967-68 conducted in five districts in different parts of India, where different tobacco usage habits prevail, 50,000 individuals were interviewed about their tobacco usage habits and examined for the presence of oral precancerous conditions. Since 1969 these individuals have been followed up annually, clinically, histologically, and cytologically, for change of habits and development of oral precancerous conditions. Follow-up surveys comprising a period of 10 years have been completed and data are now being analysed.

INVESTIGATIONS OF ORAL CANCER AND PRECANCEROUS CONDITIONS

F.S. Mehta, Tata Inst. of Fundamental Research, Basic Dental Research Unit, *Homi Bhabha Rd., Bombay 400005, Maharashtra, India* (D-IARC-79-268)

Oral cancer is the most common form of cancer in India. It is said to be frequently preceded by white lesions termed precancerous lesions. Two studies are carried out to elucidate the natural history of these oral precancerous lesions and their association with tobacco usage. About 100,00 individuals residing in Ambegaon and Junnar Taluks of Poona districts were examined for the presence of oral precancerous lesions and tobacco usage habits. The individuals with lesions and suitably matched controls are now followed up annually. About 4,000 Bombay policemen were examined in 1959 for the presence of oral precancerous lesions and tobacco usage habits. These policemen are re-examined at five-year intervals. Three follow-ups have been completed and the fourth one is now being planned.

CANCER REGISTRY COVERING MEMBERS OF SOCIAL SECURITY SYSTEM

H. Espinosa de Restrepo, Inst. de Seguridad Social, *Apartado Aereo 59-09, Medellin, Colombia* (D-IARC-79-119)

A cancer registry was initiated in the Social Security Institute in Medellin in 1972. Efforts were made to register all cases of cancer diagnosed for the first time since 1st January 1968. The objectives of this cancer registry covering a selected population are: (1) to obtain data on incidence and mortality from cancer; and (2) to undertake analytical studies to determine the relation of risk factors to specific types of cancer in groups with defined occupations and other socioeconomic characteristics. The first five years of registration showed differences for skin, larynx, and oral cancer compared to the general population. Another interesting finding was the high incidence of stomach cancer in males native to certain parts of the region (Antioquia). These findings are subjects of special studies at the present.

RETROSPECTIVE SURVEY OF HUMAN OSTEOSARCOMA IN NORTHERN IRELAND 1954-73

J.H. Elwood, Queens University of Belfast, Dept. of Community Medicine, *Belfast, Northern Ireland, United Kingdom* (D-IARC-78-501)

There are few epidemiological studies of osteosarcoma reported to date. This survey aims at ascertaining all such cases which occurred in the population of Northern Ireland with a view to describing the survivorship of these patients. Individuals having Ewing's tumour, chondrosarcoma and other primary tumours of bone will be studied - a total of around 500 patients in all, over a twenty year period of observation. Several sources of morbidity and mortality information are being used. All living patients will be followed up and re-assessed. In addition, bone biopsies from new patients having primary malignant neoplasms of bone and from a control group not having cancer of any body site will be examined for radioactivity content.

THE COINCIDENCE OF TUBERCULOSIS AND LUNG CANCER

K. Kantorova, Sanatorium for the Treatment of Tubercul. & Resp. Diseases, *Visne Hagy 05801, Czechoslovakia* (D-IARC-78-114)

Many epidemiological studies suggest higher incidence of bronchogenic carcinoma among people who suffered from tuberculosis of the lung in comparison with other populations. Among people treated at the sanatorium Kvetnica during 1960-1970 were 213 cases of bronchogenic carcinoma. Fifty four of these (25.3%) also harboured tuberculous lesions of the lung parenchyma. We want to go on and analyse the group of patients treated at our sanatorium during 1971-1978 from the point of view of coincidence of tuberculosis and lung cancer.

PROGNOSIS IN BRONCHIAL CARCINOMA IN A LIMITED GEOGRAPHICAL AREA IN FINLAND

E. Huhti, Oulun Yliopisto, Dept. of Medicine, *Kajaanintie 52 A, 90220 Oulu, Finland*

The true or overall prognosis quoad vitam of patients with bronchial carcinoma is difficult to assess in clinical materials, these usually being selected in one way or another. In this study, all cases of bronchial carcinoma from 1968 to 1971 have been collected from a limited geographical area. The patients are being followed up to determine the prognosis and to see which factors are associated with a good, and which with a poor prognosis. Special attention has been paid to the histopathology of the tumours which have been classified as suggested by a WHO committee. The study is prospective and the number of patients is about 441. Factors that will be analyzed, among others, include symptoms, smoking habits, previous radiological findings before diagnosis, site of tumour, findings at bronchoscopy and mediastinoscopy, and various biochemical characteristics. The TNM classification (as suggesed in 1966) will be used.

ENVIRONMENTAL AND OCCUPATIONAL FACTORS AND DISTRIBUTION OF LUNG CANCER AND BRONCHITIS IN UMBRIA

A. Candeli, Universita degli Studi di Perugia, School of Science, *via del Giochetto, Perugia, Italy* (D-IARC-79-327)

Umbria is one of the central regions of Italy. Some areas of this region are very different from others with respect to economic and social development, kinds of industries, density of population and climate. These differences are especially marked between the two biggest cities of the region, Perugia and Terni. Preliminary studies have shown that mortality from lung cancer and from bronchitis is higher in Terni than in Perugia. Research is in progress on atmospheric pollution in these towns which seems higher in Terni than in Perugia. For this reason it is proposed to study retrospectively the mortality and the morbidity from lung cancer and bronchitis in the two cities in relation to environment and occupation.

MESOTHELIOMA REGISTER

H.T. Planteydt, Pathologisch Anatomisch Laboratorium, *Noordpoortplein 2, Middelburg, Netherlands* (D-IARC-79-413)

In order to obtain information about the frequency of mesothelioma of pleura, peritoneum and pericardium, from 1969 onwards, all pathologists in the Netherlands were asked to cooperate in the registration of all histologically verified cases. These results are compared with the data of the Central Bureau of Statistics. In many cases slides and/or tissues were available: in a limited number of cases, electron microscopical investigations of lung tissue were done for asbestos. The occupational history was investigated extensively. Many cases are reviewed by a mesothelioma committee (Planteydet, de Jagar, van der Schoot). The geographical distribution, relation to occupational history and exposure to asbestos are recorded in several ways. From 1976 onwards registration, together with the other investigations, follows the same lines as the mesothelioma register in the United Kingdom. Since 1976 collaboration with other mesothelioma registers in the EEC has been established.

MORTALITY AND MORBIDITY SURVEY OF THE OCCUPATIONAL RISK OF DIMETHYLCARBAMAZINE-CHLORIDE (ABBREV)

A.M. Thiess, Badische Analin & Soda Fabrik Ag, Werksaerztliche Abteilung, *Brunckstrasse 56, 6700 Ludwigshafen, Federal Republic of Germany* (D-IARC-79-221)

DIMCA (dimethylcarbamylchloride) ((CH3)2 NCOCl) has been described as a multipotential carcinogen to ICR/Ha Swiss mice by application to skin and subcutis. After one year on test, a 68% incidence of tumours (46% papillomas and 22% carcinomas) resulted from application and 72% incidence of local sarcomas by subcutaneous injection. Another localization was lung tissue, though with comparatively low incidences (4-8%, compared to 0% in untreated controls). DIMCA is considered a directly acting alkylating carcinogen. The study is designed to assess the total continuously exposed work force in the production of DIMCA in order to investigate cancer incidence as suggested by carcinogenic effects in animal experiments.

CASE-CONTROL STUDY ON THE ASSOCIATION OF HERPESVIRUS WITH CERVICAL CANCER IN HUNGARY

A.S. Pacsa, Pecsi Orvostudomanyi Egyetem, Microbiology Inst., Virus Laboratory, *Szigeti Utca 12, 7643 Pecs, Hungary* (D-IARC-79-252)

The project aims to establish herpes simplex virus-specific and cytomegalovirus-specific antigen positivity in cervical cells of women with and without cervical dysplasia. Selected antigen negative and positive cases will be followed up for years registering incidence of dysplasias and tumours in both groups. By this prospective study it is intended to identify whether anaplastic changes of the cervix uteri originate

from antigen-carrying cells or not. Cervical imprints and biopsy samples are taken and coded at the Department of Oncology before sending them to the Virus Laboratory for detection of viral antigens by indirect immunofluorescence technique. It is estimated that a total of 1,000 women will be followed up.

2.2514,

DISEASES ASSOCIATED WITH HIGH CONSUMPTION OF STOUT

G. Dean, Medico Social Research Board, *73 Lower Baggot St., Dublin 2, Ireland* (D-IARC-79-291)

A suggested association between the high consumption of beer and an increase in diseases such as cancer of the colon and rectum was investigated among blue-collar workers in a Dublin brewery, who consumed more than an average amount of beer, usually in the form of stout. A study on worker mortality between 1954 and 1973 showed that they had as good an expectation of life as all Dublin males with no increased risk of disease from cancer of the oesophagus, pharynx, liver or of cirrhosis of the liver, accident or suicide, conditions normally associated with the high consumption of alcohol. The workers had a significantly increased risk of death from cancer of the rectum and also from diabetes mellitus. Further studies will be undertaken to find out if those who develop cancer of the rectum or cancer of the colon have consumed more beer during their lifetime than controls who will be men admitted to hospital in the same age-group as the cancer patients. This study will be undertaken in Dublin and in London.

EPIDEMIOLOGY OF LEUKEMIA AND APLASTIC ANEMIA

K. Aoki, Nagoya University, School of Medicine, Dept. of Preventive Medicine, *65 Tsurumai-cho, Showa-ku, Nagoya 466, Aichi ken, Japan* (D-IARC-79-362)

Japanese immigrants to Hawaii and their descendants have experienced a much higher mortality rate from leukemia and lower mortality from aplastic anemia than indigenous Japanese, reaching a mortality level similar to the Caucasians. There is no statistically significant difference in the sum of the age-adjusted mortality from all bone marrow diseases (ICD 280-289, ICD 205-209) except for lymphatic leukemia between Japanese Americans and indigenous Japanese. Genetico-epidemiological study has shown that consanguinity among aplastic anemia cases and leukemia cases was significantly more frequent than in the general population. The above data suggest that not only environmental factors but also host factors affect the incidence of these diseases.

2.2518,

CANCER MORTALITY IN UNITED STATES CARBON BLACK WORKERS

J.M. Robertson, University of Western Ontario, Faculty of Medicine, Dept. of Preventive Medicine & Epidemiology, *1151 Richmond St., London, Ontario, Canada* N6A 3K7 (D-IARC-79-79)

The cancer mortality experience of employees of four companies engaged in the production and distribution of carbon black in the United States was examined in this retrospective cohort study. All male employees with 12 or more months of service between 1935 and 1974 were study participants. The study group consisted of employees exposed to carbon black, i.e., employed on-site at a carbon black plant; the comparison group was composed of men employed in company operations other than carbon black production. The companies supplied mortality data on active and retired employees from their life insurance files. They also supplied annual employee censuses by age and years of service from which man-years at risk were calculated in 5-year age groups for quinquennial periods from the beginning of the study to employee withdrawal or termination of the study. Assuming an underlying poison distribution, the cancer mortality of the exposed (carbon black) group and the unexposed (comparison) group was compared with the expected mortality based on the sex-, age-specific cancer mortality rates of the male populations of the States in which the carbon black plants were located. Mortality due to all malignant neoplasms (I.C.D. 140-209) was lower than expectation in exposed workers but not significantly so. In unexposed workers, observed deaths due to all malignant neoplasms were significantly lower than expected (P less than 0.05). Deaths due to malignant neoplasms of the digestive organs (I.C.D. 150-159) and of the respiratory system (I.C.D. 160-163) did not exceed expectation in either group. No trend of increased mortality with increasing years of service (exposure) was evident in exposed workers (chi-square equals 0.66, d.f. equals 1; 0.25 less than p less than 0.50). The results of this study do not support an increased risk of death due to malignant neoplasms in carbon black workers. Analysis continues.

MALIGNANT NEOPLASMS AND PREVIOUS DISEASES

G. Neumann, Stuttgart Public Health Office, *Hohe Strasse 28, D7000 Stuttgart 1, Federal Republic of Germany* (D-IARC-78-218)

Clinical studies available show that patients with malignant neoplasms had fewer diseases in their history than other patients. All these studies are based only on the statements of the patients themselves. The study conducted is based on official insurance data going back up to ten years and more. The study group is composed of patients, all members of the German Health Insurance referred to a special medical service (Vertrauensaerzte). For each case with a malignant neoplasm, irrespective of site and type, two controls are selected. They must have the same sex, the same age (plus or minus two years), the same insurance (that will mean in general the same socio-economic structure), and no malignancy reported. Both types of anamnestic data are used, those given from the patient's memory and those taken from the insurance records. It was intended to have 400 cases and 2 times 400 controls. For external reasons the study had to be finished having collected 352 cases, each with two controls. The final analysis is under progress.

CANCER IN THE SINDHI-SPEAKING POPULATION

D.J. Jussawalla, Tata Memorial Hospital, Dept. of Surgery & Chemotherapy, *Dr. Ernest Borges Marg, Parel, Bombay 400012, Maharashtra, India* (D-IARC-79-266)

Greater Bombay, population 5.97 million (1971 census), has various groups whose mother tongues and places of origin are different. One such group are the Sindhis, identified on the basis of their mother tongue, who migrated en masse after the creation of Pakistan from the province of Sindh. The 1961 census of India enumerated approximately 95,000 Sindhi-speaking people in Bombay city. Sindhis are a comparatively fair-complexioned, hard-working, business-oriented people who differ widely in their habits and social customs from other groups in Bombay. The specific aim of this investigation is to study cancer frequency in this Sindhi-speaking population. Efforts are being made to compare the Sindhi-speaking groups with the other Marathi- and Gujarati-speaking peoples.

EPIDEMIOLOGICAL STUDY OF ACUTE LEUKEMIA IN ADULTS AND CHILDREN (ABBREV)

J.E. Parker, Lions Gate Hospital, *E. 13th St., Vancouver, British Columbia, Canada* V7L 2L7

In a retrospective study, an association between cases of acute leukemia in some adults and between other cases of leukemia in childhood or in other adults, has come to light within the suburban community of North and West Vancouver, there being a variable and sometimes long latent period between cases. A prospective questionnaire study of all newly diagnosed cases of acute leukemia within the above suburban community is being carried out, attempting to define a relationship between cases as to time, place and person. This is considered under the following headings: date of diagnosis, age, sex, duration of symptomatology, family history of malignancy, contact with other cases of lymphoreticular malignancy in family or friends, addresses and change of address (domestic and employment) within the above community, exposure to domestic animals. It is proposed to compare these findings with age matched controls in non-leukemic cases admitted to Lions Gate Hospital.

CARCINOEMBRYONIC ANTIGEN IN AN UNSELECTED POPULATION

I.R. Mackay, Walter & Eliza Hall Inst. for Medical Research, Clinical Research Unit, *c/o Royal Melbourne Hospital, Melbourne, Victoria 3050, Australia*

The adult population of Busselton, which is relatively closed and stable, has since 1966 been the subject of ongoing surveys, marked by accession rates in the order of 90 percent. The surveys entail health questionnaires, medical examinations and numerous biochemical and other health indices such as electrocardiograms. In particular, the occurrence of cancer and changes in smoking habits are under close scrutiny. The immunochemical method for detection of carcinoembryonic antigen (CEA) in serum is a microradioimmunoassay, appropriate for this study, in that it requires only 0.25 ml of whole serum. The 'cut-off' level for positivity was five ng per ml. The first phase consisted of CEA estimations on the 1969 sample. The total tested was 2,372. There were 73 positive tests, about 3 percent of the population, and cancer has occurred in nine (12 percent) of these 73 subjects. Cigarette smoking was found to be strongly associated with CEA in blood, and could have accounted for raised CEA levels in about one half of those with CEA but no demonstrable cancer. The population was bled again in 1975, the total tested being 3,120 adults, and is being resurveyed for the prevalence of CEA. Under new assay conditions, the 'cut-off' level for a raised CEA in the present assay was taken as 15 ng per ml for comparability with data from the 1969 survey. The data are still under analysis, but two negative aspects in regard to population screening for CEA are already evident: (1) there is a very low correlation among subjects between raised levels of CEA in 1969 and raised levels in 1975, and (2) there is little if any association of raised CEA levels with subsequent development of cancer.

THE EPIDEMIOLOGY OF LEUKEMIA IN GREATER BOMBAY

D.J. Jussawalla, Tata Memorial Hospital, Surgery & Chemotherapy, *Dr. Ernest Borges Marg, Parel, Bombay 400012, Maharashtra, India* (D-IARC-78-253)

Nothing is known regarding the epidemiology of various forms of leukemia, particularly in children and adolescents, in India. In the Bombay registry, between 1964 and 1972, 1,064 cases of leukemia were registered. 204 (ICD, 8th revision) Lymphatic Leukemia 310 cases; 205 Myeloid Leukemia 469 cases; 206 Monocytic Leukemia 23 cases; 207 Other and Unspecified Leukemia 262 cases; Total 1,064 cases. The aim of this study is to determine: 1. Incidence, age, and sex distribution of various types of leukemias by religion and geographic area at the city ward level; 2. Statistics of mortality will be examined in the light of reported variations in incidence and demographic variables; 3. The address of each leukemia patient as recorded in detail will be plotted on an area map of the city for a study of time-space clustering.

2.2524,

THE EPIDEMIOLOGY OF LUNG CANCER (A RETROSPECTIVE STUDY)

D.J. Jussawalla, Tata Memorial Hospital, Dept. of Surgery & Chemotherapy, *Dr. Ernest Borges Marg, Parel, Bombay 400012, Maharashtra, India* (D-IARC-79-265)

In India, tobacco is widely used for chewing and smoking, and the incidence rates of lung cancer, both in men and women in Bombay, are lower than in Western countries in spite of the fact that smoking of the bidi and cigarette is steadily increasing. However, in a retrospective study, Notani and Sanghvi (1974) observed that the incidence of lung cancer is higher among bidi smokers than among cigarette smokers. One thousand nine hundred eight cases of cancer involving the trachea, bronchus and lung have been recorded at the Bombay Cancer Registry between 1964 and 1972. All the available patients will be interviewed to obtain detailed information on their smoking habits, and data on education and socioeconomic status will be collected on a detailed proforma. These cases will be closely matched with the healthy resident population of Greater Bombay. The matching parameters will be age, sex, religion and socioeconomic status. Appropriate relative risks in tobacco users and non-users, in relation to the disease pattern, will be worked out by the statistical techniques as suggested by Cornfield (1951), and Mantel and Haenszel (1959). The mortality of lung cancer in the Greater Bombay population will be examined in the light of reported variation in incidence, for demographic variables such as age, sex, etc. For this purpose, mortality statistics have been obtained from the Section on Vital Statistics of the Municipal Corporation of Bombay.

EPIDEMIOLOGIC STUDY OF BREAST CANCER

D.J. Jussawalla, Tata Memorial Hospital, Surgery and Chemotherapy, *Dr. Ernest Borges Marg, Parel, Bombay 400012, Maharashtra, India* (D-IARC-78-249)

The incidence rate of breast cancer is low in India, but certain social groups (religious communities) are observed to be high risk groups for breast cancer. In this study, attempt is made to analyze the incidence rate of breast cancer in certain communities like Parsis, Hindus from Sind and others. By analyzing both case-control (hospital) differences and comparing them with population rates, the role of high risk factors like familial history and menstrual-marital-pregnancy history would be studied. Intercommunity comparison of these risk factors would be attempted. Detailed information on about 1,500 breast cancer cases has been obtained so far in this study. Appropriate controls are chosen from among the hospital patients and include those women coming to the hospital who have no evidence of any disease and also those with minor inflammatory diseases, except in the breast. Long-term follow-up studies have been set up for selected benign lesions of the breast to understand the malignant potential of such lesions.

2.2527,

EPIDEMIOLOGICAL STUDY OF INCIDENCE, MORBIDITY & NATURAL HISTORY OF SOME TYPES OF CANCER, BY RELIGIOUS GROUP, IN THE BOMBAY AREA POPULATION

D.J. Jussawalla, Tata Memorial Hospital, Dept. of Surgery & Chemotherapy, *Dr. Ernest Borges Marg, Parel, Bombay 400012, Maharashtra, India* (D-IARC-79-263)

A study carried out by Jussawalla and others (1970) examined the differences observed in the site incidence of cancer between the Parsi community and the total population of Greater Bombay. This investigation revealed disease differences of appreciable epidemiologic interest. Thus, cancers of the buccal cavity, pharynx, larynx, oesophagus and cervix uteri were less common in the Parsis. On the other hand, the Parsi rates were higher at sites such as the female breast, body of uterus, ovary, prostate and skin and for all leukemias. The purpose of this study is to determine the incidence of various types of cancer by religion. The numerical distribution of religions in Bombay is the following: Hindus 4,110,746 (68.85%), Muslims 843,358 (14.13%), Christians 375,265 (6.29%), Parsis 64,667 (1.08%), Jains 244,721 (4.10%), Buddhists 284,303 (4.76%), and Sikhs 42,862 (0.71%) out of a total population of 6 million persons. Statistical analysis of the recorded data on cancer will be carried out as follows: (1) Crude and age-specific rates by sex, year and primary sites in various religious groups; (2) Age-adjusted rates, as suggested by Doll and others, by sex and primary sites; (3) Comparison of incidence rates for religious groups in Greater Bombay with that of other races in the United States and other countries.

PROSPECTIVE STUDIES ON CANCER EPIDEMIOLOGY BASED ON CENSUS POPULATION IN JAPAN

T. Hirayama, Ministry of Health & Welfare, National Cancer Center, Epidemiology Division, *5-1-1 Tsukiji, Chuo-ku, Tokyo 104, Tokyo, Japan* (D-IARC-79-389)

To study the health consequences of selected risk factors including cigarette smoking, alcohol drinking, diet (rice, fish, meat, milk, green-yellow vegetables, soybean paste soup, pickles, hot tea), occupation, marital status, number of children, age at first marriage, length of breast feeding, etc., a prospective population study has been in progress in 29 Health Center Districts in 6 prefectures in Japan since the autumn of 1965. A total of 265,118 adults, 122,261 males and 142,857 females aged 40 years and above, 91-99 percent of the census population, were interviewed and followed by establishing a record linkage system between the risk factor records, a current residence list obtained by special annual census, and death certificates. The extent of change in each risk factor was checked in 1971 and 1976. For 35,345 deaths, including 9,324 deaths from cancer, which occurred during twelve years of follow-up, crude age-adjusted and age-specific rates (for both age at enrollment and attained age) for each cause of death were calculated according to the risk factors listed above. In addition, matched pair and matched group analysis was conducted. A multifactor-multidisease risk matrix was completed and high and low risk groups for cancer were identified. For instance, the risk enhancing effect of cigarette smoking and risk lowering effect of daily intake of green-yellow vegetables was observed for lung cancer. Study is still in progress (currently in 14th year of follow-up).

EPIDEMIOLOGY OF MALE GENITAL TRACT CANCER

D.J. Jussawalla, Tata Memorial Hospital, Dept. of Surgery & Chemotherapy, *Dr. Ernest Borges Marg, Parel, Bombay 400012, Maharashtra, India* (D-IARC-79-264)

A series of 1,003 male genital cancers (prostate 514, testis 182, penis 307) were recorded in Greater Bombay during 1964-72. The specific aims of the investigation are: 1. To study the natural history and epidemiology of these tumors; 2. to determine the morbidity and mortality from such tumors; 3. to study the practice of circumcision in relation to penile cancer in different religious groups; and 4. to determine whether any reasons can be ascertained for the low incidence of male genital cancer in Greater Bombay.

INCREASING RISK FOR BREAST CANCER - ASSOCIATION WITH FAMILIAL, GENETIC AND REPRODUCTIVE FACTORS

N.E. Day, Centre International de Recherche sur le Cancer, Epidemiology & Biostatistics Unit, *150 Cours Albert Thomas, 69372 Lyon Cedex 2, France* (D-IARC-79-173)

OBJECTIVE: To determine whether there are hereditary characteristics which might be of use in the identification of women having a high risk of developing breast cancer. The unique facilities available in

Iceland for the study will be utilized. These include (1) a nationwide cancer registry functioning since 1954 (about 800 cases); all cases of breast cancer diagnosed between 1910 and the start of the cancer registry are on file, (2) a computer-based National Roster since 1952, (3) a family linkage file linking every individual alive after 1910 to his parents and children, and (4) a cervical screening clinic which has seen more than 80% of the female population in Iceland born between 1905 and 1945. Information is collected on reproductive history and age at menarche, to be used as control data. If an excess risk is found, an effort will be made to (1) correlate familial risk with recognized epidemiological risk factors for breast cancer, (2) quantify the risk attached to different types of relationships, and (3) for each class of relative, examine the association, if any, between the degree of risk and the age of the proband case and age of appearance of cancer among these relatives.

2.2532,

COMPARISON OF THE EFFECTS OF PLAIN AND FILTER CIGARETTE SMOKING UPON THE INCIDENCE OF LUNG CANCER

J. Rimington, North Western Regional Health Authority, Greater Manchester Mobile Chest X Ray Service, *Shaw Heath, c/o St. Thomas Hosp., Stockport SK3 8BL, England, United Kingdom* (D-IARC-79-685)

OBJECTIVES: To: (1) determine smoking habits in relation to the amount and type of cigarettes smoked (filter or plain); (2) ascertain the lung cancer incidence over a period of at least four of five years; and (3) relate lung cancer incidence to type of cigarette smoked.

METHODS: Large numbers of male mass radiography volunteers, at least 40 years of age, have been questioned and answers recorded on special forms. Subsequent X-ray examinations have excluded men with existing lung cancers. Yearly follow-up will be accomplished by comparing notifications of lung cancer cases of the Manchester Regional Cancer Registration Bureau with these special forms. Most deaths from lung cancer are registered even if the cases have not been registered before death. Information on smoking habits has been computer processed.

INCIDENCE OF TESTICULAR TUMORS WITH EMPHASIS ON POSSIBLE RURAL PREPONDERANCE AND OCCUPATION 2.1835
AUSTRALIAN PETROLEUM INDUSTRY HEALTH STUDY 2.1838
DIET, ALCOHOL, AND HORMONAL STATUS IN COLORECTAL CANCER 2.1840
RISK FACTORS FOR FEMALE CANCERS 2.1841
MONITORING THE OCCUPATIONAL ENVIRONMENT FOR CARCINOGENS - A PILOT STUDY IN MONTREAL 2.1843
LATENT PERIODS OF CHEST CANCERS IN CHRYSOTILE WORKERS 2.1845
BLADDER CANCER IN THE CENSUS DIVISION OF CHICOUTIMI, QUEBEC 2.1849
CANCER MORTALITY AMONG VINYL CHLORIDE WORKERS IN SHAWINIGAN, QUEBEC 2.1850
POSSIBLE INFLUENCE OF ENVIRONMENTAL POLLUTION ON CANCER MORTALITY IN A POPULATION LIVING NEAR A VINYL CHLORIDE POLYMERIZATION PLANT 2.1851
MORTALITY PATTERNS IN A POPULATION LIVING NEAR A COPPER-REFINING PLANT IN ROUYN-NORANDA, QUEBEC 2.1852
PRECANCEROUS CONDITIONS OF THE STOMACH 2.1858
EPIDEMIOLOGICAL STUDY OF LARYNGEAL CANCER 2.1862
EPIDEMIOLOGICAL INVESTIGATION ON LARYNGEAL CANCER 2.1871
MORTALITY STUDY ON THE OCCUPATIONAL RISK OF ACRYLONITRILE PROCESSING 2.1880
MORTALITY AND MORBIDITY SURVEY OF OCCUPATIONAL RISK OF ETHYLENE AND PROPYLENE OXIDE IN CHEMICAL PRODUCTION OF BASF, LUDWIGSHAFEN, GERMANY 2.1881
CASE-CONTROL STUDY IN COPENHAGEN OF URINARY BLADDER TUMORS 2.1888
A RETROSPECTIVE STUDY OF CANCER IN RELATION TO A SPECIFIC ENVIRONMENTAL FACTOR - WATER NITRATE 2.1890
WOOD WORKERS AND CANCER 2.1898
EXPOSURE TO IRON OXIDE AND CANCER INCIDENCE 2.1899
HERBICIDE EXPOSURE AND CANCER INCIDENCE AMONG RAILROAD WORKERS 2.1900
MORTALITY AMONG FOREST WORKERS 2.1901
CANCER OF THE BLADDER IN OPIUM ADDICTS 2.1905
COMPARATIVE STUDY OF ALCOHOLISM AND CANCER OF THE HEAD AND NECK 2.1921
A CASE-CONTROL STUDY ON CANCER AND MALFORMATION IN CHILDHOOD 2.1922
ASBESTOS-RELATED CHEST DISEASES IN BEDIRLI-YESILOVA-BURDUR 2.1923
EPIDEMIOLOGICAL ASPECTS OF ASBESTOSIS AND MALIGNANT TUMORS 2.1924
A MORTALITY STUDY OF CHRYSOTILE ASBESTOS WORKERS 2.1926
MORTALITY STUDY OF UK ACRYLONITRILE WORKERS 2.1933
A RETROSPECTIVE COHORT STUDY ON MALIGNANT NEOPLASMS IN WORKERS OF A CHROMATE MANUFACTURING PLANT IN TOKYO 2.1945
CHLOROMETHYL-METHYL ETHER STUDY 2.1959
RECORD LINKAGE FOR DRUG MONITORING 2.1966
MORTALITY IN CHRYSOTILE ASBESTOS TEXTILE WORKERS - IMPLICATIONS FOR HYGIENE STANDARDS 2.1967
CANCER INCIDENCE AMONG EMPLOYEES IN THE CHEMICAL INDUSTRY 2.1968
AFLATOXIN AND LIVER CANCER IN SWAZILAND 2.1970
INVESTIGATION OF MORTALITY AND MORBIDITY PATTERNS IN CADMIUM WORKERS IN THE UNITED KINGDOM 2.1971
STUDY OF HAIR DYE USERS 2.1977
CORRELATION BETWEEN CONSUMPTION OF DAIRY PRODUCTS AND HUMAN LEUKEMIA AND LYMPHOMA 2.1979
CANCER OF THE OESOPHAGUS 2.1981
OCCUPATIONAL CANCER RISK ESTIMATION IN CHEMICAL INDUSTRY 2.1982
MORBIDITY SURVEY IN RELATION TO OCCUPATIONAL EXPOSURE TO VINYL CHLORIDE 2.1984
RISK IN WORKERS EXPOSED TO BENZENE 2.1985
LUNG CANCER MORBIDITY IN WORKERS EXPOSED TO INDUSTRIAL CHEMICALS 2.1987
URINARY CYTOLOGICAL INVESTIGATIONS FOR DETECTION OF BLADDER CANCER AMONG RUBBER WORKERS EXPOSED TO PHENYL-2-NAPHTHYLAMINE 2.1988
NASAL CARCINOMA IN NICKEL WORKERS 2.1998
RELATION BETWEEN AIR POLLUTION AND CANCER 2.2005
NUTRITION AND CANCER OF THE COLON - A CASE-CONTROL STUDY IN SPECIFIC GEOGRAPHIC REGIONS OF THE NETHERLANDS 2.2006
PRENATAL EVENTS AND CANCER RISK IN THE OFFSPRING 2.2008
CASE-CONTROL STUDY OF ESOPHAGEAL CANCER 2.2012
EPIDEMIOLOGICAL STUDY ON CANCER PATIENTS 2.2013
RELATIONSHIP BETWEEN AIR POLLUTION AND CANCER IN JAPAN 2.2018
CANCER OF THE ESOPHAGUS - A CASE-CONTROL STUDY 2.2026
A PROSPECTIVE SURVEY OF CANCER IN LESOTHO 1970-1974 2.2028
COHORT STUDY OF REFINERY WORKERS 2.2031
MORTALITY EXPERIENCE AMONG POLYCHLORINATED BIPHENYL WORKERS 2.2032
A FOLLOW-UP STUDY OF LEPROSY PATIENTS 2.2034
EPIDEMIOLOGY OF THYROID CANCER 2.2035
IS ANGIOSARCOMA OF THE LIVER ASSOCIATED WITH VINYL CHLORIDE MONOMER EXPOSURE IN SOUTH AFRICA? 2.2042
CANCER AMONG RUBBER WORKERS AND ESTIMATION OF CANCER RISK BY URINARY THIOETHER EXCRETION OF WORKERS 2.2048
OCCUPATIONAL, ATMOSPHERIC AND DIETARY FACTORS AND HABITS ASSOCIATED WITH EPIDERMOID CARCINOMA OF THE BUCCAL CAVITY IN CHILE 2.2050
CANCER MORTALITY IN THE LAST TWENTY YEARS IN SPECIFIC COUNTIES AND CITIES OF MINNESOTA 2.2057
HEALTH EFFECTS OF ASBESTOS EXPOSURE IN NAVAL SHIPYARD WORKERS 2.2064
RESPIRATORY EFFECTS OF CHLOROMETHYL ETHERS 2.2078
EPIDEMIOLOGICAL STUDIES ON THE FREQUENCY OF TUMORS IN FISH FOUND IN POLLUTED WATERS AND THOSE FOUND IN UNPOLLUTED WATERS 2.2084
EPIDEMIOLOGIC SURVEY ON HAWAII RESIDENTS 2.2086
EPIDEMIOLOGY OF HEPATIC ANGIOSARCOMA 2.2089
CANCER AND ORAL CONTRACEPTIVES 2.2090
CANCER MORTALITY AFTER ARSENICAL THERAPY FOR SYPHILIS 2.2093
INCIDENCE OF SECOND SQUAMOUS CANCERS OF THE HEAD AND NECK IN SMOKERS AND THOSE WHO HAVE CEASED SMOKING 2.2096
MORTALITY EXPERIENCE OF WORKERS IN THE PAINTING TRADES IN THE U.S. AND CANADA 2.2097
CANCER EXPERIENCE OF VINYL CHLORIDE POLYMERIZATION WORKERS 2.2099
NATIONAL LARGE BOWEL CANCER PROJECT 2.2100
MORTALITY EXPERIENCE OF TEXTILE DYERS AND PRINTERS 2.2101
TRI-COUNTY STUDY OF CANCER OF THE MOUTH, OESOPHAGUS, PHARYNX, LARYNX, STOMACH, COLON AND RECTUM 2.2112
EPIDEMIOLOGY OF MALIGNANT MELANOMA 2.2116
MORTALITY EXPERIENCE OF BRAKE REPAIR AND BRAKE MAINTENANCE WORKERS IN NEW YORK CITY 2.2118
SELENIUM OCCURRENCE AND HUMAN CANCER MORTALITY - FAT AND BEEF CONSUMPTION AND HUMAN CANCER MORTALITY 2.2120
CASE-CONTROL STUDY OF USE OF OXIDATIVE HAIR DYES AMONG FEMALE CANCER PATIENTS 2.2121
CASE-CONTROL STUDY OF OCCUPATION AND CANCER 2.2127
MEDICAL SURVEILLANCE AND INTERVENTION - BLADDER CANCER 2.2133
EPIDEMIOLOGY OF STOMACH CANCER AND NITRATES IN CHILE 2.2135
CANCER AMONG CHILDREN OF NURSE ANESTHETISTS 2.2147
CANCER RISK AND CYCLOPHOSPHAMIDE USE 2.2148
EPIDEMIOLOGICAL STUDY OF DIETARY COMPONENTS AND CANCER DEVELOPMENT 2.2154
ECOLOGICAL, STATISTICAL, ETHOLOGICAL, AND RELATED BIOLOGICAL STUDIES ON AIR POLLUTION, SMOKING AND OTHER ENVIRONMENTAL VARIABLES (ABBREV) 2.2156
EPIDEMIOLOGICAL STUDIES OF CANCER 2.2159
SURVEILLANCE FOR DRUGS THAT MAY BE CARCINOGENIC 2.2161
STUDY OF THE ROLE OF DIET IN THE ETIOLOGY OF COLON CANCER 2.2162
DIET AND COLON CANCER IN A LOW RISK POPULATION 2.2166
LATE EFFECTS OF CANCER TREATMENT IN CHILDREN INCLUDING SECOND MALIGNANT NEOPLASMS - CHILDREN'S INTERNATIONAL CANCER INVENTORY 2.2167
INTERNATIONAL CASE-CONTROL STUDY OF BLADDER CANCER 2.2169
MORTALITY EXPERIENCE OF NITROSAMINE-EXPOSED WORKERS 2.2179
TRACE ELEMENTS AND CANCER 2.2187
CORRELATION OF EPIDEMIOLOGICAL AND METABOLIC PARAMETERS IN RELATION TO LARGE BOWEL CANCER 2.2188
